SUPPLEMENT TO "THE ELECTRICIAN," NOVEMBER 4, 1892.

PRINCETON UNIVERSITY LIBRARY PAIR>
32101 017687284

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XXIX.

FROM MAY 6, 1892, TO OCTOBER 28, 1892.

(RECAP)

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1892.

Digitized by Google

INDEX TO "THE ELECTRICIAN."

VOL. XXIX.

General Alphabetical Index.

A

Aberdeen, 310, 521, 623
Aberystwith, 569
Absorption of Light by Ground Glass, 51
Accidents, 3, 134, 162, 503, 527
Accrington, 410, 574, 603
Accumulator Cars at Barking, 443
Accumulator Cars at Birmingham, 417, 443
Accumulator, Commercial, 660
Accumulator Efficiency, 211
Accumulators, Loss of Charge in the Negative Plates of, M. Kugel, 134, 148
Accumulator Patent Litigation in France, 417
Accumulator Plates, Preservation of, 324
Actinism, 110
Action at a Distance, 475
Albert Medal of the Society of Arts, 83
Allen Dynamos and Engines, 579
Alternate Current and Battery Systems of Distribution Controversy, 374
Alternate Current Difficulties, 60
Alternating Currents, Best Frequency for, 83
Alternators.
A new, 650
Patin, 117
Pyke and Harris, 37
Westinghouse, 689
Aluminium, 27, 299, 504
Aluminium Plating, 383
Aluminium, Societe de l', de Neuhausen, 185
Aluminium v. Copper, 352
American Association for the Advancement of Science, 520
American Institute of Electrical Engineers, 55
American Patent Law, Reform of, 2
Ampere-Centimetre, 108, 113, 242
Ampere Hour, 213
Animal Electricity, 161
Antimony in Electrolytic Copper, 445
Antwerp, 26
Arc, Counter Electromotive Force of the Voltaic: by F. Stenger, 101
Arc Lamps: by W. Geipel and H. Kilgour, 246
Arc Lamps, Thermal Control for, 506
Arc, Notes on the Light of the Electric: by Alex. P. Trotter, 11. *Discussion*, 65
Arc, Physics of the Voltaic: by Silvanus P. Thompson, 460
Armatures, Dissipation of Heat in, 27
Armoured Cables, Patent, 134
Associated Chambers of Commerce, and Telephones and Telegraphs, 552
Association Française pour l'Avancement des Sciences, 631
Aston, 653
Atmospheric Electricity, 299, 384, 632, 685
Atomic Weight of Oxygen, 162
Australasian Telegraph Rates, 621
Australian Train Lighting, 685
Ayrton-Mather-D'Arsonval Galvanometer, 336
Ayrton, Presentation to Prof., 54
AYRTON, Prof. W. E.
Efficiency of Transformers at Different Frequencies, 615
Workshop, Ballistic and other Shielded Galvanometers, 174
Azores Cable, 28, 161, 284

B

BACON, Lieut. R. H.
Some of the Uses of Search Lights, 688
Bacon on the Conversion of Air into Water, 160
Bacup, 340
Ballarat School of Mines, 185
Barking Accumulator Cars, 443
Barnet, 265, 685
Barnsley, 270, 383
Bartholdi's Statue of Liberty, Electric Lighting of, 551
BARTON, E. H.
Temperature Variation of the Magnetic Permeability of Magnetite, 432
Bath, 653
Bauti's (Dr. A.), Experiments on the Magnetisation of Nickel under Mechanical Stresses, 161
BEDELL, Dr. F.
Propagation of the Current in a Cable Containing Distributed Static Capacity and Self-Induction, 619, 634
Bedford, 324, 351
Belfast, 521, 569, 623, 679
Belgian 500 H.P. Dynamo, 565
Berlin, 212, 383, 574
Berwick, 545
BIDWELL, SHELFORD.
On the Changes Produced by Magnetisation in the Length of Iron and Other Wires Carrying Currents, 172
Bills (Electrical) in Parliament, 3, 83
Bilston, 410, 569
Birmingham, 659
Birr, 653
Bishop Stortford, 410
Bismuth Battery, 27
Blackburn, 161, 383
Blackpool, 237, 299, 521, 545, 603, 659
Blockley, 679
BLONDLOT, R.
On the Rate of Propagation of Electromagnetic Oscillations in Insulating Mediums and on Maxwell's Relation, 356
Board of Trade and Electricity Meters, 415, 435
"Board of Trade" Unit, 54
Boilers, Management of: by W. Geipel and H. Kilgour, 194
Boiler Test, 162
Bolton, 569
BONNIER, GASTON.
The Influence of the Electric Light on the Structure of Herbaceous Plants, 649
Boston, Electric Cars in, 687
Bournemouth, 109, 299
Bowness, 653
Boys' (Prof. Vernon) Photographs of Flying Bullets at the Royal Society Conversazione, 159
Bradford, 653
Bradford Central Station, 2, 474, 551
Bradford Electrical Tramcars, 62, 70
Bradford, Electric Traction Experiment at, 1, 212
Bradford, Supply of Electricity at, 6, 526, 683
"Brain" Covered Conduit System of Electric Traction, 485
Brake Dynamometer, An Electric, 671
Bray, 299, 623
Breath Figures: by W. B. Croft, 258
Brescia Telephone Exchange, 457
Breslau, 27, 270
Bridgend, 569, 679
Brighton Municipal Supply, 207, 332, 384, 653, 684
Brillie Meter, 170
Bristol, 4, 383, 417, 653, 679, 705
British Association, 271, 323, 348, 381
at Edinburgh, 394
Conference on Electrical Standards, 445, 474
Electrical Standards Committee, 371, 415, 447, 462 (Report)
List of the Electrical Papers read, 405
Money Grants, 434
National Physical Laboratory, 447, 492
Sketch of some of the Electrical Papers in Section A, 397.
Units Discussion, 433
British South Africa Company's Telegraphs, 28
BROWN, J.
Voltaic Cells with Fused Electrolytes, 305
BROWN, Prof. CRUM.
Electrolytic Synthesis of Dibasic Acids, 436
Bruce's Signalling Balloon, 270
Brussels, 350
Bucharest, Public Works in, 153
Budapest, 243
Bumsted and Chandler's High Speed Engine, 37
BURCH, E. P.
Electric Railway Motor Tests, 303
Burnley, 184
Buxton, 569, 623

C

Cable and Land Line Interruptions and Repairs, 4, 26, 53, 161, 185, 270, 324, 685
Cable Companies, Appointments in, 351, 383
Cable Containing Distributed Static Capacity and Self-Induction, Propagation of the Current in a: by F. Bedell and A. C. Crehore, 619, 634
Cable Duplications, 53, 161
Cable Museum, 551
Cable, Proposed French Azores-Hayti, 284
Cable Relays: by Walter Judd, 636
Cable Stations, Electric Lighting of, 134
Cable Survey in the Pacific, 271
Cables, River, 383
Calcutta, 623
Camberwell, 375, 623, 705
Cambridge, 527, 551, 685
Cambridge University, Mechanical Science Tripos, 134, 149, 166
Canada, Consolidation of Edison Interests in, 685
Canadian Patent Law, 350
Candle Power of Arc Lamps Arranged Two in Series on 110-Volt Circuits, A Mode of Varying: by P. Vitte, 185
Carbon Brushes, 270
Carbon, First Visible Colour of Incandescent, 686
Cardiff, 410, 417, 623, 705
Carlow, 550, 604, 659
CARTER, E. T.
Gearing, 425, 453, 513, 559, 587, 641, 666, 602
Thomson's Law of Economy, 248
Traction, 58
Castings, Magnetising Molten Iron, 550
Central Institution, 650
Central London Railway, 25, 185
Central Station Data in Germany, 426
Central Station Exhaust Steam, Utilisation of, 272
Central Stations of Europe, 271
Central Station Projects, 374
Ceylon as a Source of India Rubber, 326
Charlottenburg, 82, 271
Chatham, 417
Chelmsford, 653
Chelsea, Electric Lighting in, 527
Chicago Exhibition, 43, 83, 184, 269, 350, 446, 475, 543, 550
Electric Lighting Conduit, 329
Electric Lighting, 4, 40, 55, 137, 313
Electrical Trade Section, 312, 415
English Engineering Exhibits, 4
Foreign Electric Lighting, 336
Good Roads and the, 53
Pricing of Goods at, 220, 253
Proposed Congress, 27, 337
Sales at the, 520
Space, Allotment of, in Electrical Building, 40
Telephone Exchange, 54
Chicle as an Insulator, 551, 635
Chiswick, 153, 270, 705
City and Guilds of London Institute, 382
City and Guilds of London Institute and the Corporation, 184
City and South London Railway, 133, 183, 227
City, Electric Lighting of, 109, 417, 526, 536, 631
City Lighting Curves, 536
City of London Electric Lighting Company and the New Telephone Company, 109, 631
Civil List Pensions, 283
Clark Cell, On the: by Dr. Kahle, 516
Club Lighting, 213
Coast Communication, 29, 186, 383, 503, 550, 574, 649, 659, 683, 685
Coast Communication, Royal Commission on, 299, 325, 351, 418
Coatbridge, 438
Colchester, 376, 383
Colgate Secondary Battery, 537
Cologne Central Station, 15, 185
Commerce and Coercion, 690
Commercial Electrolysis, Problems of: by J. Swinburne, 367, 389
Commercial Telegrams, 350, 352
Communication (Telegraphic) with Lighthouses and Lightships, 29
Commutators: by F. M. Weymouth, 245, 307, 333, 357

COMPANIES' MEETINGS, REPORTS, DIVIDENDS, STATUTORY RETURNS, &c.

(Abbreviations :—Mtg., Meetings of Shareholders; Rpt., Reports of Directors; Div., Dividends; Stat., Statutory Returns. Traffic Returns are not indexed here, as they are inserted at regular periods.)

Abell's Electrical Engineering Company—131
African Direct Telegraph Company—207; Rpt., 316; Stat., 707
Anglo-American Telegraph Company—Rpt., 319; Mtg., 376; Div., 321, 599
Anglo-General Electric Light Company—105
Anglo-Portuguese Telephone Company—207
Atlas Electrical Appliances Company—Mtg., 79
Babcock and Wilcox—295; Div., 500; Mtg., 571
Bath Electric Light Company—105
Bell Telephone Company of America—Div., 157
Benham and Froud—Stat., 105
Berlin Elektricitatswerke—Div., 651
Birmingham Central Tramways Company—Rpt., 441; Mtg., 470
Birmingham Electric Supply Company—Stat., 23
Blackpool Electric Tramway Company—Mtg., 599
Blockley Electric Lighting and Manufacturing Company—Stat., 267
Bournemouth Electricity Company—239.
Bradford Mutual Electric Lighting Company—320
Brazilian Submarine Telegraph Company—49; Mtg., 20, 680; Stat., 131; Div., 131, 627; Rpt., 655
Brighton and Hove Electric Light Company—Stat., 655
British Electrical Tramways and General Syndicate—49
British Guiana Electric Lighting and Power Company—Mtg., 599
Brush Electrical Engineering Company—523; Stat., 23; Div., 547; Rpt., 595; Mtg., 624
Buenos Ayres Electric Light Company—Stat., 655
Callender's Bitumen Telegraph and Waterproof Company—Stat., 235; Div., 681
Cambridge Electricity Supply Company—131
Chamberlain and Hookham—Stat., 181
Chelsea Electricity Supply Company—Mtg., 46; Stat., 347
Chili Telephone Company—Mtg., 293; Stat., 413
Chloride Electrical Storage Syndicate—Stat., 105
City and South London Railway Company—Rpt., 346; Mtg., 410
City of London Electric Lighting Company—599; Rpt., 471; Mtg., 498; Stat., 627
Commercial Cable Company—157; Div., 548
Compagnie Continentale Edison—Rpt., 79
Compagnie Française du Telégraphe de Paris à New York—Mtg., 320
Compagnie de l'Industrie Electrique Genévoise—413
Consolidated Telephone Construction and Maintenance Company—Div., 49; Rpt., 130; Mtg., 155; Stat., 627
Crompton and Co.—Rpt., 320; Mtg., 378, 624
Croydon Tramways Company—Mtg., 412

COMPANIES' MEETINGS, &c. (*continued*)—
Cuba Submarine Telegraph Company—379; Rpt., 412; Mtg., 440
Cutting, Douglas and Co.—239; Stat., 655
Cuttriss, Wallis and Co.—Stat., 295
Davis and Timmins—Stat., 23
Direct Spanish Telegraph Company—Div., 347; Rpt., 547; Mtg., 570
Direct United States Cable Company—Rpt., 319; Mtg., 377; Div., 656
Eastbourne Electric Lighting Company—Stat., 413
Eastern and South African Telegraph Company—105, 207; Stat., 471
Eastern Extension, Australasia and China Telegraph Company—Mtg., 18; Div., 240, 571; Rpt., 706
Eastern Telegraph Company—347, 681; Div., 239, 571; Rpt., 294; Mtg., 342
Edison-Gower-Bell Telephone Company of Europe—131
Edison-Swan United Electric Light Company—Div., 267; Rpt., 292; Mtg., 315; Stat., 471
Electric and General Investment Company—132; Mtg., 154; Stat., 295
Electric Arms and Ammunition Syndicate—Stat., 707
Electric Construction Corporation—182
Electric Date and Time Stamp Company—707
Electric Fittings Hiring and Maintenance Company—Stat., 523
Electric Lamp Company—707
Electric Sewage Utilisation and Improvements Company—321
Electric "Sun" Lamp and Power Company—105
Electrical Coal Cutting Contract Corporation—239
Electrical Installation Company—Stat., 707
Electrical Power Storage Company—Rpt., 294; Mtg., 318; Stat., 441
Electrical Standardising, Testing and Training Institution—Stat., 207
Electrical Supplies and Fittings Company—Stat., 707
Electrical Works Construction and Maintenance Company—Stat., 49
Electricity and Electrical Engineering Newspaper Company—Stat., 49
Electricity Supply Company for Spain—Stat., 157
Electricity Supply Corporation—105, 131; Mtg., 23; Div., 442
Electro-Chemical Syndicate—707
Elieson Electric Supply Company—131
Elmore's American and Canadian Patent Copper Depositing Company—Mtg., 22; Stat., 157
Elmore's French Patent Copper Depositing Company—21, 321; Stat., 131; Mtg., 104
Elmore's German and Austro-Hungarian Company—Rpt., 130; Mtg., 157; Stat., 295
Elmore's Metall-Aktien Gesellschaft—79
Engineering Exchange—267
Evered and Co.—Stat., 267; Div., 600
Globe Telegraph and Trust Company—Rpt., 319; Mtg., 345; Stat., 523; Div., 572
Grange Syndicate—23
Great Northern Telegraph Company—Mtg., 21; Div., 24
Greenwood and Batley—182; Stat., 267
Halifax and Bermudas Cable Company—Rpt., 412
Halifax Mutual Electric Light and Power Company—Stat., 627
Harding and Son—239
Hastings and St. Leonard's-on-Sea Electric Light Company—Stat., 23
Head, Wrightson and Co—Stat., 627
Henley's (W. T.) Telegraph Works Company—Stat., 79; Div., 548
Hobart Tramway Company—49; Mtg., 267
Hong Kong Electric Company—Mtg., 471
House-to-House Electric Light Supply Company—Stat., 23
Hulett (D.) and Co.—Stat., 627
India Rubber Estates Company—267
India Rubber, Gutta Percha and Telegraph Works Company—240; Stat., 49; Mtg., 266; Div., 321
Indo-European Telegraph Company—Stat., 157; Div., 705
International Elektricitäts Gesellschaft—347
Islington and General Electric Supply Company—105, 131
Johannesburg Lighting Company—Stat., 49
Keighley Electrical Engineering Company—Stat., 627
Kensington and Knightsbridge Electric Lighting Company—Div., 321, 380
Laing, Wharton and Down Construction Syndicate—Stat., 627
Lancashire Electric and Engineering Company—Stat., 239
Latimer Clark, Muirhead and Company—Stat., 207
"Lightning"—239
Liverpool House-to-House Electricity Company—49
Liverpool Overhead Railway Company—347; Rpt., 413; Mtg., 440
Llanelly Electric Light and Power Company—Stat., 79
London Platino-Brazilian Telegraph Company—Stat., 131
London Tramways Company—Mtg., 294
Madras Electric Tramways Company—Stat., 627
Manchester Edison-Swan Company—Rpt., 318; Stat., 413
Manlove, Alliott and Co.—131
Marshall, Sons and Co.—Stat., 181
Mather and Platt—131
Metropolitan Electric Supply Company—Mtg., 47; Stat., 157
Mexican Telegraph Company—347
Midland Electric Light and Power Company—Stat., 627
Mix and Genest—Div., 24
Monte Video Telephone Company—707
National Telephone Company—655; Div., 207; Rpt., 266; Mtg., 291
Newcastle and District Electric Lighting Company—Div. 347
New Australian Electric Company—681

COMPANIES' MEETINGS, &c. (*continued*)—
New Cadogan and Belgrave Electric Supply Company—627
New Portable Electric Lamp and Power Syndicate Company—321
New Shanghai Electric Company—Mtg., 104
New Telephone Company—347
New York Belting and Packing Company—Mtg., 132
New Zealand Electrical Syndicate—681
Northern Counties Electric Light and Power Supply Company—681
Notting Hill Electric Lighting Company—Stat., 23
Oriental Telephone Company—Mtg., 48; Stat., 105
Paris and New York Cable Company—292
Petroleum Engine Company—Div., 682
Phonopore Company—572
Phosphor Bronze Company—Stat., 49
Pioneer Telephone Company—Stat., 295; Mtg., 440
Pontypool Electric Light and Power Company—Stat., 655
Potter (T.) and Sons—50
Pretoria Lighting Company—Rpt., 626
Ransomes, Sims and Jefferies—Stat., 181
Reading Electric Light Company—Stat., 499
Regent Portable Electric Lamp and Lighting Company—267
Reuter's Telegram Company—79; Mtg., 129; Stat., 239; Div., 628
River Plate Electricity Company—Stat., 655
Ruston, Proctor and Co—106; Stat., 523
St. James's and Pall Mall Electric Light Company—207, 681
St. Paul's Printing and Publishing Company—Stat., 79
Sheffield Telephone Exchange and Electric Light Company—Mtg., 319; Stat., 523
Siemens Brothers and Co.—Stat., 499
Société Française des Télégraphes Sous-Marins—Rpt., 347
Société Générale des Téléphones—Div., 347
Southampton Electric Light and Power Company—Stat., 181
South American Telegraph Company—627
Submarine Cables Trust—322; Mtg., 21
Sunderland and District Electricity Supply Company—49
Swan United Electric Light Company—Div., 50
Syndicate of Electrical Engineers—Stat., 79
Taunton Electric Lighting Company—156; Mtg., 104
Telegraph Construction and Maintenance Company—268; Mtg., 294
Telephone Company of Austria—Rpt., 320; Stat., 571; Div., 628
Telephone Company of Ireland—Rpt., 412; Mtg., 470
Telephone Manufacturing Company—Stat., 413
United River Plate Telephone Company—Rpt., 316; Mtg., 345; Stat., 471
Ward Electric Car Company—Stat., 49
Water Primary Battery Company—267
West African Telegraph Company—Div., 207; Rpt., 238; Mtg., 344
West Coast of America Telegraph Company—208; Rpt., 207; Mtg., 237; Stat., 321
West India and Panama Telegraph Company—Rpt., 48; Mtg., 78; Stat., 181
Western and Brazilian Telegraph Company—22; Mtg., 44; Stat., 157
Western Counties and South Wales Telephone Company—347; Mtg., 156, 206, 293
Western Union Telegraph Company—158; Div., 600
Westminster Electric Supply Corporation—Div., 413, 442
Wiener Privat Telegrafen Gesellschaft—848
Willans and Robinson—Stat., 49
Woking Electric Supply Company—Stat., 49
Woodhouse and Rawson United—268

COMPANIES (NEW ELECTRICAL, &c.) REGISTERED—
The following Companies have been Registered under the Limited Liability Acts during the past half-year:—
Abell's Electrical Engineering Company, 48
Agricultural Machinery Company of France, 79
Akester Electrical Syndicate, 655
Albright and Wilson, 320
American Insulated Wire Company, 346
Armstrong's Electric Light and Power Company, 547
Bates Steel Company, 599
Bickle and Co., 79
Birmingham Iron and Steel Stamping Co., 681
Broadbottom Gas Company, 379
Bryncelyn Gaslight and Coke Company, 266
Cambridge Electric Supply Company, 105
Capon, Heaton and Co., 413
Carbon Battery Co., 627
California Gas, Water, and Electric Light Company Syndicate, 547
Central Ironworks Company, 320
Central Rail Traction Company, 320
Collier-Marr Telephone and Electrical Manufacturing Company, 441
Cutting (R. C.), Douglas and Co., 79
Dibasic Iron and Steel Company, 599
Dowie and Handyside, 379
Electric Clock Company, 181
Electric Lamp Company, 263
Electrical Coal Cutting Contract Corporation, 207
Electrical Company, 321
Electrical Installation Company, 130
Elieson Accumulator British Patent Syndicate, 681
Engineering Exchange, 23
Expanded Metal Company, 207
Globe Engineering Company, 599
Hampton (Edwin), 105
Hersey Brothers, 295
Holloway Electricity Supply Company, 266
Hope-Jones Electric Organ Company, 267
Hove Electric Lighting Company, 413
Howell (J. C.), 295
Jonas and Colver, 413
Jordan (C.) and Sons, 599
Kennedy Storage Battery Company, 499

COMPANIES (NEW ELECTRICAL, &c.) REGISTERED (*continued*)—
Lithanode and General Electric Company, 295
Livoni and Bowman, 321
London and Hampstead Battery Company, 79
London and Suburban Messenger and General Agency Company, 207
London Electric Manufacturing Company, 239
London Electric Wire Company, 157
Lynch and Co., 413
Mather and Platt, 48
Meiter Syndicate, 239
New Electro Metallurgical Syndicate, 627
Nottingham Machinists' Company, 523
Pacific and European Telegraph Company, 239
Payne, Gallwey, Pickering and Co., 23
Piggott (Thos.) and Co., 295
Powditch (J. R.) and Co., 655
Railway Electric Reading Lamp Company, 267
Renton, Gibbs and Co., 441
Richmond Electric Light and Power Company, 295
Root's Petroleum Motor Syndicate, 347
Saunders (John), 707
Schiele Union Engineering Co., 655
Sheffield Electric Light and Power Company, 23
Simpson (Jas.) and Co., 295
Slag Reduction Company, 379
Smokeless Boiler and Engineering Company, 23
Societé de l'Electricité de la Mediterranée, Souchier et Cie., 379
Sperryn, McDonald and Co., 441
Theatre Electrical and Specialities Production Company, 321
United Electric Sewage and Chemical Syndicate, 413
United Electrical Tramways, 707
Universal Arc Lamp Company, 321
Veale and Co., 131
Western Counties Electric Light and Power Syndicate, 23
Whiteley (John) and Sons, 23
Competition, 332
Condensers and Pumps: by W. Geipel and H. Kilgour, 419
Condensers, On the Dielectric of, by W. H. Preece, 430
Conduit, Love Electric Traction, 328
Constants, The Constancy of Electricity Meter, 455
Contracts, Electric Lighting, 576
Control (Electrical) of Street Cars, 15
Cooking by Electricity, 81, 552
Copenhagen Electric Lighting, 263
Copper, 3, 82, 133, 135, 162, 270, 351, 445, 603
Copper, American Practice in the Electrolytic Refining of, 222
Cork, 631
Cork Gas Consumers' Association, 444
Cost and Profits of Central Stations, 16
Cotton Manufacture, Electricity in, 3
Cranes, Electric Travelling, 630
CREHORE, A. C.
Propagation of the Current in a Cable Containing Distributed Static Capacity and Self-Induction, 619, 634
CROFT, W. B.
Breath Figures, 258
Crompton-Howell Battery at Bradford Central Station, 6
Crookes (Mr.) and Nitrogen Burning in Air, 210
Croydon, 623
Crystal Palace Exhibition, 445
Experiments, 27
List of Awards, 257
Testing of Meters, 183
Wiring, 197
Customs' Officers, Electric Lamps for, 603
Cuttriss Carbon Submarine Relay, 133
CUTTRISS, CHARLES.
Cuttriss Carbon Relay for Submarine Cables, 147

D

DARRIEUS, G.
Lead Accumulators from a Chemical Standpoint, 359
DAY, JOSEPH.
On a New Form of Gas Engine, 423
DEADMAN, H. E.
On the Applications of Electricity in the Royal Dockyards and Navy, 539, 564. *Discussion*, 565

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 729.—Vol. XXIX. FRIDAY, MAY 6, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The President of the Board of Trade having cordially approved and Lord Kelvin having acquiesced; after the word "unit" in the Provisional Orders of this year, the words "hereinafter called a kelvin" will be introduced. The correspondence upon this subject will shortly be published.

The question of the suitability of the name is beyond criticism, and no exception need be taken to the use of a name of one who is still living. The question of the need for any name is another matter, and one on which we have on a former occasion expressed some doubts. Many of our readers will agree with us that in discussing the supply of electrical energy the simple word "unit" is sufficient, and no more ambiguity arises than when "a thousand" is alluded to in talking of gas supply. It must be admitted that the word "unit" is sometimes employed to denote an integral element of the generating plant of a station, but that is the fault of those who gave it this name. The word "unit" is also employed to express the output of a dynamo, though the word "kilowatt" is slowly gaining ground. There is no confusion here. A 100-kilowatt dynamo generates 100 units in an hour. We have never felt the need of any other word than "unit," but then we can generally manage, without much difficulty, to avoid using the expressions "electromotive force" or "electricity." Those who really feel the want of a better word than "unit" ought to be satisfied; and time will show how many there are who prefer the "kelvin." The schoolboys of the future will learn to say:—

1,000,000 ergs	make	1 meg-erg.
10 meg-ergs	,,	1 joule.
3,600 joules	,,	1 watt-hour.
1,000 watt-hours	,,	1 kelvin.

We have given the new word a fair trial in some of the following Notes.

The conversazione of the Royal Society on Wednesday was in no way less interesting than usual. Dr. J. T. Bottomley dealt with Teslaic discharges in vacuum tubes without electrodes, using a quart bichromate battery and a small coil. These tubes were made several years ago. Mr. Wimshurst showed Leyden jars with coatings of insulated wire; Dr. Oliver Lodge, besides some beautiful optical effects, illustrated a possible interpretation of the rod and cone structure of the retina by the electrical oscillations in cylinders vibrating across a diameter. Captain Holden exhibited a number of electrical instruments, and Prof. Crookes provided brilliant high frequency experiments. Messrs. Pyke and Harris showed an inductor dynamo and a large number of vacuum tubes worked at 100,000 volts from a transformer provided with oil insulation, the oil being kept in continuous circulation through a dehydrator of sodium. A current of three amperes at 100 volts from the main of the London Electric Supply Company was used. An arrangement of condensers, formed of pieces of tinfoil on a large sheet of glass, enabled vacuum tubes of different sizes to be run in parallel.

The attraction of the evening was the exhibition of the photographs by Prof. Vernon Boys, of flying rifle and pistol bullets. The electrical arrangements were of great interest, and the results were marvellous. It might be thought that this is a mere feat of photography, and that it differs only in degree from "kodaking" an express train. But in the hands of Prof. Boys the flying bullet teaches as many physical truths as a soap bubble, and is the more interesting since the hyperbolic air waves in front, the trail and vortices in the wake, their inclinations, mutual reactions, and other subsidiary phenomena have never before been visible or even thought of. These photographs have been shown at a lecture at South Kensington and again this week at the Royal Victoria Hall. We strongly recommend our readers to endeavour to be present at the next public demonstration, of which we hope due notice will be given.

There is every reason to expect that Mr. Holroyd Smith's electric traction experiment at Bradford will result in the adoption of the system by the energetic Corporation of that town. There is no question here of competition with horses. Horse traction is out of the question on most of the Bradford lines, which are worked with noisy, dirty, and expensive steam locomotives, drawing "two-deckers" seating 68 passengers. The Corporation have allowed Mr. Holroyd Smith to make a demonstration on a length of 660 yards of line in the middle of the town, and it must be admitted that a more difficult piece of line would be hard to find. The first 170 yards has a slight incline, averaging 1 in 150. Then 293 yards, with a rise of 60 feet, having a gradient of 1 in 13¼, and on this hill the street curves sharply round to the right with a radius of about 35 feet. After this is a length of 293 yards, with a gradient of about 1 in 90. Up this hill a car weighing 6½

Digitized by Google

tons can carry 43 passengers at about 8 miles an hour, the mechanical work alone, Mr. HOLROYD SMITH informs us, being about 35 H.P. During an experimental run three times up and down the line, taking a fully loaded car up the hill on each occasion, besides a little manœuvring on the level, $1\frac{1}{3}$ kelvins were used.

A TROLLEY line is at present used at Bradford, and it rests entirely with the Corporation whether, in the event of the adoption of electric traction, this shall be made permanent, or whether a slotted conduit shall be used. The current is provided at present from the two smaller dynamos of the electric supply station, and thus the local authorities can satisfy themselves with ease as to that part of the cost. It is an excellent feature of this experiment that the Corporation who own the lines should be in a position to settle the system of conductors, and should be able to provide the current themselves, thus reducing the matter to a simple question of mechanical engineering.

THE motors and driving gear, which have been built by Messrs. EASTON and ANDERSON, present several interesting features, which we hope to describe on a future occasion. Having such a stiff piece of line to encounter, more driving power than is actually needed has been provided. There are two "dual armature" motors. That is to say, there are four armatures and two pairs of field-magnets. Each armature drives a separate wheel by means of worm gearing, the details of which are the outcome of a considerable amount of experiment. Ball thrust-bearings are used. These armatures can be coupled all in series, or in two parallel sets in series, or all in parallel; resistances are also provided. With the second arrangement a car designed to accommodate 36 passengers but loaded with 47, climbed the hill and curve at about five miles an hour.

A VERY ingenious use has been made of these four armatures on the Bradford car for applying a powerful brake going down hill. They are disconnected from the supply of current, and are all joined in series; the resistance being low, they generate a considerable current which allows the car to move only at a creeping pace. There is a tendency to stop dead and then to run on a little, and as soon as the motors begin to generate, to stop again. Mechanical brakes and reversing gear are of course provided as well. The work has hitherto been completely successful. A rumour was current in the district some weeks ago that two armatures had burned out. This was without foundation, and arose from the failure of the end-insulation of the commutators. The current does not exceed 75 amperes, and is generally limited to 50, there being no difficulty at all in this respect.

JUST as we go to press we learn that General HUTCHINSON has inspected and has officially passed the Bradford electrical traction system, which will now run regularly for public service.

WE learn from the *Scientific American* that Representative STOUT, of Michigan, has been moved by the recent Berliner transmitter scandal to bring forward a resolution requesting the Committee on Patents to ascertain "whether any modification of the patent law is necessary to protect the public against undue monopoly." Our American contemporary points out in characteristic phraseology that if the Supreme Court upholds the Berliner patent, "the public will be cornered again, and subjected to prolonged corporate squeezing," and sensibly suggests the abolition of the present system of official examination into the novelty of inventions, with its tedious delay in issuing patents and its mysterious "interference" proceedings.

PATENT literature, like all other printed matter, has enormously increased of late years; and investigations into the novelty of inventions, if they are to afford any guarantee to the patentees who, in the end, pay the piper for them, must, as years go on, become more and more costly and tedious. The principle of *caveat emptor* seems peculiarly applicable to those who take out patents; these should be nothing more than outward visible signs that the holders of them consider themselves entitled to certain privileges, and if anyone thinks otherwise let the law decide. If the Governments which favour the system of examination regarded infringers as social pests, and took it upon themselves to defend the validity of the patents which they issue, it would be another matter altogether.

THE Americans are notoriously great revellers in statistics, and if their figures were more frequently of the kind presented at the recent annual meeting of the Thomson-Houston Company at Middleton (Conn.) we should have good cause to envy them this amusement. The share capital of the Thomson-Houston Company is $10,000,000, say two millions sterling. Business during the past year, we are told, has not been quite so active as could be wished; nevertheless, it has been found possible to pay 7 per cent. on the preferred stock, 16 per cent. on the ordinary shares, and to add over £300,000 to the "surplus account," which now stands at about £1,500,000. At the end of 1882, the business turnover at the Boston office was only some £85,000; to-day it amounts to considerably more than £2,000,000. The activity in local company enterprise has slackened, nevertheless 118 concerns were launched in 1891, making a total of 873 companies employing 100,000 arcs and 800,000 incandescents, all manufactured by the parent firm. As to railway work, no less than 204 are at work or under contract, having an aggregate mileage of 2,500 miles. When will a leading English electrical manufacturing firm be able to pay a *bonâ fide* 16 per cent. dividend and put by a sum equal to one-seventh of its capital? We reel at the thought of the dinners which will have to be given in order to properly celebrate the event.

SUPPLY stations are built for those that pay for them, and Papers describing them are written for the audience to whom they are addressed. The unaccountable reticence of Mr. SHOOLBRED at the Society of Arts on Wednesday last on the subject of the lamp connections at Bradford was fortunately defeated by the frank information given by Mr. BAYNES. The

Digitized by Google

number of lamps connected which is the chief item of commercial importance and interest to engineers, is at present equivalent to 19,000 eight-candle lamps. The earning capacity per lamp, which Mr. SHOOLBRED attempted either to conceal or to ignore, is 20 kelvins per annum; or 9s. 7d. per lamp fixed, at the date of the last balance-sheet. The excuse was put forward, that a local authority has nothing to do with lamps, that a statement of the number of lamps is "misleading" and "delusive." If not interesting to Mr. SHOOLBRED, the capital per lamp fixed, and the revenue per lamp, were items which some of his audience thought to be worth eliciting. Mr. FRANK BAILEY pointed out that the average proportion of lamps burning at the heaviest load was about 50 per cent. of the lamps connected, showing a much better ratio than in London, where 33 per cent. is the rule. He added that a careful record of the number of lamp connections gave a valuable warning against the overloading of the plant during fogs.

As a catalogue of the plant put down by Messrs. SIEMENS and others and an assurance that it was running well, the Paper of Mr. SHOOLBRED fulfilled its purpose; but had it not been for the discussion, which we hope will appear in the *Journal* of the Society of Arts, several facts of real interest would not have been forthcoming. Mr. CROMPTON pointed out that from a rough calculation, the coal appeared to come to about ½d. per kelvin (he did not use this expression, but we want to see how it looks), while the cost per ton was about one-third of the London price, and asked whether any figures could be given showing the performance of the boilers. Mr. BAYNES was able to give this information. Each pound of fuel evaporated 6·84lbs. of water, and this, allowing for the working pressure of 140lbs. per sq. in. gave 7·59lbs. of water evaporated from and at 212°, per pound of fuel.

A VALUABLE feature of the balance sheets of undertakings such as the electric supply of Bradford is that being in the hands of the Corporation they are free from trade bias. Their testimony, as Mr. CROMPTON put it, is untainted; but Mr. GARCKE pointed out that, on the other hand, local authorities are tempted to present a favourable account of their doings, and that they have great facilities for distributing their expenditure over the accounts of the different departments. He observed that no figures were given for rent of offices, clerks, insurance, and other items. Mr. ALBRIGHT and others inquired whether the 2½d. per kelvin included depreciation of mains, &c. Mr. SHOOLBRED, in reply, pointed out that neither interest nor sinking fund were included, and that depreciation would form part of the latter. One other omission will, we hope, be remedied in the next report of this station, viz., the ratio between the units generated and the units sold. With resistances inserted in the feeders, and batteries even of the CROMPTON-HOWELL make, this ought not to be neglected.

MR. ALEX. SIEMENS made one or two remarks about the advantage of placing gas, water, and electric supply in the hands of a common authority, and thought that storage batteries were useful only for toy stations where a few hundred amperes would suffice for the light load. He followed a rather commonplace remark about the flattening out of the load curve when use of motors is extended, by an oracular hint at some new thing, whether invention or application of electrical energy we know not; but "something that will startle battery people!"

APROPOS of mysteries, the copper market is said to be staggering under the shock occasioned by the discovery of a new conducting material. If this is nothing more than aluminium at 2d. a pound we have heard of that before; but speaking of new metals, we hope shortly to present to our readers an account of a new, and probably very important, process for making bar copper direct from the ore.

Electrical Bills in Parliament.—The London County Council (Subway) Bill was read a third time in the House of Commons last week.

Electricity in Cotton Manufacture.—We have received from the Electrical Department of the Agricultural and Mechanical College of Auburn (Ala), a sample of the first cotton "ginned" by electricity.

Derby.—At a meeting of the Town Council, on Wednesday, a recommendation that the Corporation should undertake the lighting of the central part of the town by electricity and devote £30,000 to the work was unanimously adopted.

Obituary.—The death is announced of the Vicomte de Vougy, who was at the head of the French Telegraph Service from 1854 to 1870, and who was most energetic in bringing about the first International Telegraph Conference of 1865.

Copper.—Copper is 12s. 6d. a ton lower in price than it was a month ago. The visible supply of the metal is 53,828 tons, compared with 54,311 tons on March 31st. During the month the deliveries in England and France were 9,441 tons, and the supplies 8,958 tons.

Preston.—About half-past nine o'clock on Saturday morning last an explosion took place in the National Electric Supply Company's mains in Lancaster-road. At the time stated, a workman was going down with a lighted candle to examine a main. It is supposed gas had got into the mains.

Institution of Engineers and Shipbuilders in Scotland.—At the annual general meeting of this Institution held last week, premiums of books were awarded to Mr. Henry A. Mavor for his Paper on "The Development of Electric Distribution;" and to Prof. Andrew Jamieson for his Paper on "The Electric Lighting of Public Buildings."

Vertical Beams.—Lieut. Froud, secretary of the Shipmasters' Society, has written to the papers stating that to help in further testing the "vertical beam" idea, Mr. Ronald Scott has volunteered to project a vertical beam of light from the Crystal Palace at 9 to 9:15 every week-day evening during the present month. The committee of the society would be glad to receive the notes of any observer.

Telephone Trunk Wire Extensions.—The Exeter Telephone Exchange was last week connected with Newton, Torquay, and Plymouth. The trunk tolls from Exeter (in each case for three minutes' conversation are as follows:—Newton Abbot (22 miles), 6d.; Torquay (28½), 6d.; Paignton (32), 6d.; Brixham (40½), 9d.; Dartmouth (44), 9d.; Totnes (38½), 9d.; Buckfastleigh (45), 9d.; Ashburton (48), 9d.; Plympton (58), 9d.; Plymouth (62½), 9d.; Rame Head (98½), 9d.

Accident with an Electrical Coal Cutter.—A fatal accident took place at Glass Houghton Colliery, Castleford, on Wednesday. Mr. W. P. Bannister, an electrical engineer, about 22 years of age, was experimenting with a coal-cutting machine, when by some mishap he got entangled in the machine, and

Digitized by Google

his left leg was cut completely off by the coal cutter, the other leg being severely crushed. He was removed to Leeds Infirmary, where he expired shortly afterwards.

International Horticultural Exhibition.—The electric lighting of this Exhibition is carried out with 210 10-ampere arcs, run 30 in series, eleven 40-ampere projectors being used in the arena. The dynamo plant consists of eight 30-lighters, two compound 17-unit machines for the projectors, and two Mordey alternators capable of supplying 1,000 glow lamps. The engines and boilers are by Davey, Paxman and Co. The whole of the above was installed by Mr. A. H. Wood within five weeks.

Bristol.—The Electrical Committee of the Town Council held a meeting last week for the purpose of selecting tenders for dynamos and boilers for the Bristol central station. There were about a dozen tenders for dynamos, and eight to ten for boilers. The lowest tender for dynamos was that of Messrs. Siemens Brothers and Co., at £14,011, and the lowest for boilers that of Messrs. Tinker Brothers, of Hull, at £7,450, and these were accepted by the committee. For dynamos the figures ranged from £14,011 to about £20,000, and for boilers from £7,450 to about £10,000.

Telephone Wires and Electric Light Mains in Glasgow.—On behalf of the New Telephone Company, application has just been made to the Glasgow Corporation Electric Lighting Committee to enter into an arrangement whereby the Company would be enabled to lay their telephone wires alongside of and at the same time as the electric light cables that are shortly to be put down within the central area of the City. The Committee have considered the application, and have resolved to recommend that it is not desirable or expedient that the Corporation should enter into any such arrangement.

The Signal Light of the House of Commons.—In answer to a question with reference to this matter, Mr. Plunket stated in the House of Commons, on Monday, that the cost of the signal light per Session was £60. The initial cost of substituting an electric light, as suggested, would not be less than £750, and its annual cost £150. He believed, however, that it would be possible to rearrange the existing light so that with the assistance of lenses it could be made visible all round, at an initial expense of, approximately, £400 or £500. He could not undertake to carry out any change this Session, but would take care that it was considered in connection with next year's estimates.

The Electric Lighting of the Chicago Exhibition.—"The course of events in regard to the award of contracts for lighting the World's Fair, as well as for the power plant," says the *Electrical Engineer* of New York, "has been somewhat extraordinary, and on the whole the situation is one to be regretted. . . . We note some very vigorous comments in the Chicago newspapers on the figures, and must admit that a most unfortunate showing has been made. Such an enormous reduction can only be interpreted by the public to mean either that a tremendous profit was sought for in the first instance, or else that the work has now been taken at a terrible loss to keep out competitors. Both aspects of the case give a bad impression."

Royal Institution.—At the annual meeting of this Institution, held on Monday, Sir James Crichton-Browne in the chair, the annual report of the Committee of Visitors for the year 1891 was read and adopted. The real and funded property now amounts to above £83,000, entirely derived from the contributions and donations of the members. Fifty new members were elected in 1891. The books and pamphlets presented amounted to about 248 volumes, making, with 517 volumes (including periodicals bound) purchased by the managers, a total of 765 volumes added to the library in the year. The following were unanimously elected as officers for the ensuing year:—President, the Duke of Northumberland; treasurer, Sir James Crichton-Browne; secretary, Sir Frederick Bramwell.

English Engineering Exhibits and the Chicago Exhibition.—The following extracts from a letter by Mr. R. H. Tweddell to last week's *Engineering* are decidedly to the point:—

"As I before said, it is all a matter of business. The sentimental features of Exhibitions began and ended with that of 1851. The promoters of such shows and their electrical tea gardens are after all only advertising agents, and then not half so efficient or customer-reaching in their effect as the columns devoted to that purpose in your own and similar leading journals. . . . . The question of exhibiting, so far as mechanical engineers are concerned, seems to be entirely a monetary one. Will any return result to compensate for the outlay? I think not—not even for specialities—and for ordinary engineering work the duties are prohibitive so far as our sending work to the States is concerned. I do not think we need fear French or German competition; and so far as the Columbian Exhibition is concerned, interesting and wonderful as it promises to be in many respects, I do not see how it is to affect the engineering trades. The question of the command of South American and other markets will be decidedly the relative cost of labour, transport and materials in the States and in Great Britain."

Incandescent Lighting of the Chicago Exhibition.—After nearly two weeks' deliberation, says the *Western Electrician* of April 23rd, the World's Columbian Exposition, acting on the recommendation of Directors R. C. Clowry and Charles H. Schwab and Electrical Engineer Sargent, of the construction department, has decided to award the contract for furnishing the 93,044 incandescent lights needed for the World's Fair to the Edison General Electric Company at the rate of $5.95 per lamp for the period of time named in the specifications. The price named includes dynamos, station apparatus, mains, inside wiring, sockets, lamps, and renewals. The Edison Company's original price for this work was $18.49 per lamp. At the rate agreed upon the contract will amount to $553,611.80. The arc lighting will cost about $120,000. The offer of the Western Electric Company to furnish generating capacity for 2,500 lamps for $1 will be accepted.

St. Pancras Vestry Electric Light Station Dynamos.—There are eleven Kapp-Willans combinations at this station. The engines are of the latest triple expansion type, and the dynamos are Messrs. Johnson and Phillips' central station multipolar machines, manufactured under Mr. Kapp's patent. Of these eleven dynamos six are wound for an output of 680 amperes at a maximum of 130 volts; three are wound for an output of 680 amperes at a maximum of 145 volts. The compactness of the combination is shown by the fact that each 90-unit steam dynamo only requires an area of 10ft. 6in. by 5ft. 6in. of floor space. At the official trial at Thames Ditton the combination showed a consumption of steam equal to 18·65lb per E.H.P. per hour. The remaining two dynamos are wound for an output of 90 amperes, at a maximum of 580 volts, for supplying current to the Brockie-Pell street lamps, or for charging in series four sets of 60 secondary batteries at the central station. These dynamos are separately excited from the low-pressure circuit. At the official trial of this combination the steam consumption was equal to 19·61b. per E.H.P. per hour. At present there are only 28 arc lamps in use, which are worked in four parallels of seven in series, but it is likely that these will shortly be increased to 90, and would be worked in nine parallels of 10 in series, thus taking up the load of one dynamo, the other being held in reserve. The lamps already installed are of the double carbon 32-hour type, being specially designed for street work. Each lamp is erected on an ornamental cast-iron post at a height of 25ft. from ground level to centre of the arc; the distances between posts vary from 160ft. to 245ft. In a chamber at the base of each post a double-pole switch, mounted on an oil insulator, is fitted, which switch allows of the lamps being cut out of circuit. Alternate lamps are put on different circuits, so that at any specified time half of the lamps can be switched out at the central station, leaving the intermediate lamps still in circuit As is well known, the whole of the works have been designed and carried out by Prof. Henry Robinson.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 659.*)

9. Underrunning.—By referring to the cable chart and splice list, it is often possible to avoid the making of a new splice close to an old one, and so adding unnecessarily to the joints in the cable. For instance, while picking up towards a fault,

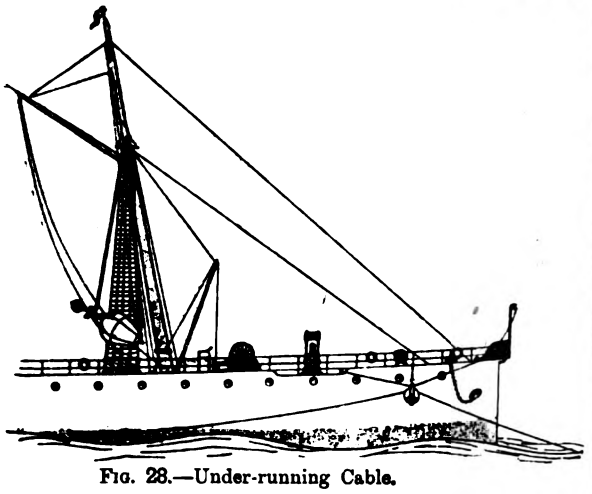

FIG. 28.—Under-running Cable.

say that the tests make it about three miles further on. This estimate may or may not be correct, and the fault may still be seaward when the cable is cut at this distance. At any rate, if the chart indicates a previous splice existing one mile beyond

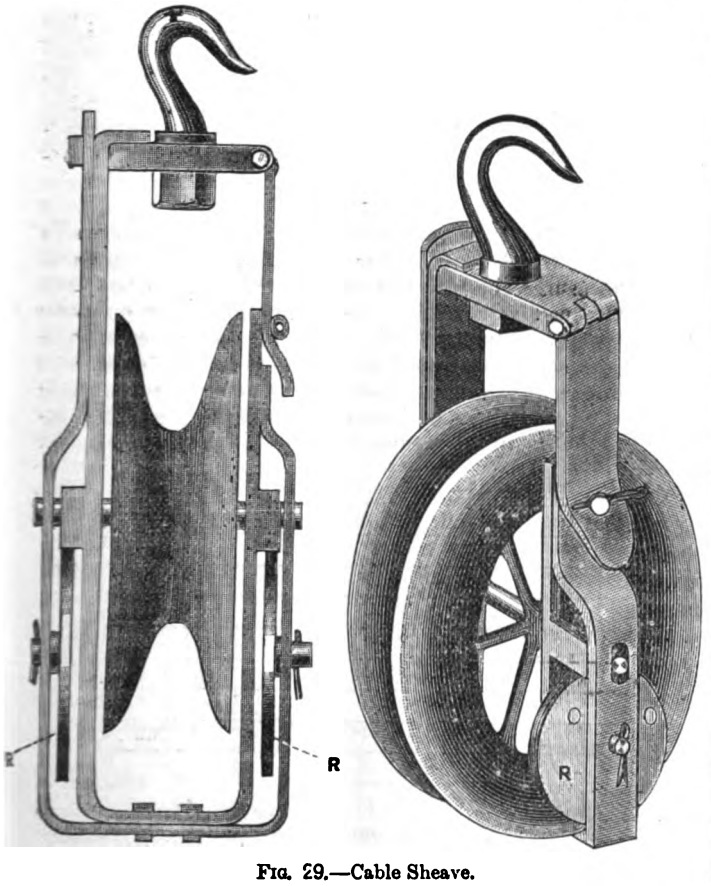

FIG. 29.—Cable Sheave.

the estimated distance, it will be better to pick up the four miles and cut at the splice, so saving an extra joint in the cable.

Again, when repairing in shallow water, it is sometimes possible to avoid a fresh splice in a heavy shore end by underrunning up to a previous splice. Say the fault to be removed is within ten miles of shore, and that the tests locate it within two or three miles of a splice about eight miles out.

In cases such as this it is advisable to make the first cut at the splice, and the ship will accordingly grapple for the cable as near to this splice as possible. When hove up it is seen by the type of cable towards which direction the splice lies, and, without cutting, the cable is underrun up to the splice. This is effected by lifting the bight off the grapnel and passing it over a large sheave suspended at the bows, and guyed in position by chains as shown (Fig. 28). The sheave employed is two or three feet in diameter, and is in principle similar to a snatch-block. In Fig. 29 one of these portable cable sheaves is shown, in which friction rollers, R R, are applied, making the running of the sheave very true and easy. On steaming slowly ahead the cable is drawn up over the loose sheave of the block, over which it rides back into the sea. This is continued till the splice appears, when the bight is heaved in and the cable cut and tested. The ship then buoys the end which tests all right, and picks up on the other end to the fault in the usual way.

Up to about 15 miles from shore, and in shallow water up to about 40 fathoms, it is often practicable to repair a cable without calling in the services of the repairing steamer. Either a good size steam tug, or a barge taken in tow by a tug, may be speedily rigged with all the necessary gear. The barge in tow is the more serviceable as regards the room on board for coiling and for fixing a temporary paying-out brake. This kind of repairing work near shore with lighters and steam tugs we shall refer to again, but as regards under-running, the repair of a total break near shore is very well effected in this manner. The sheave for underrunning is rigged up on the fore part of the barge exactly as described above, and the cable is first dredged for close in shore. The bight is then put in the sheave, and the tug steams ahead. When a steam tug alone is used, the sheave is rigged on the weather side so that the vessel can swing clear of the cable to leeward. By doing so, she can be steered better and her head kept up to the cable. The strain on the seaward end of the cable becomes visibly lessened as the break is approached, and the tug is eased down while the end is got up and stoppered on to the mooring-chain for buoying. The other end is then dredged for, cut and spliced on to a length of spare cable on the barge, and payed out to the buoyed end. The final splice is then made and the cable dropped overboard. Mr. A. C. F. Webb, the first to introduce under-running, which he practiced in repairing the Hague cables from the Dutch coast in 1853, relates in his interesting Paper "On the Practical Operations Connected with Paying Out and Repairing Submarine Telegraph Cables," read before the Institution of Civil Engineers, in February, 1858, how he effected the repair of a break 10 miles out from this coast during the severe winter of 1854, in a Dutch fishing smack. The difficulties he surmounted in this, one of the earliest instances of under-running, were peculiarly great. So much ice abounded that it was deemed too risky to employ a steam tug for the purpose, and the fishing smack being dependent upon the wind, became useless in the finest and most favourable weather. At such times the cable was pulled in over the sheave by manual labour, and the smack in this way propelled. The cable was taken over a sheave fixed at the head of the vessel close to the bowsprit, and then passed over a block hanging on the weather side of the vessel forward of the rigging, so that the cable passed over a portion of the fore deck. After successfully under-running the cable up to the break and buoying the end, all work had to be suspended for ten days, the ice meanwhile carrying away the buoys; but the whole of the cable was under-run a second time and buoyed again, and this time the other end was dredged up and a piece spliced in successfully. The repair, which involved great anxiety and danger, occupied altogether three months, during which Mr. Webb and his assistants were exposed for whole nights to the bitterest weather.

10. Capacity of Tanks.—While cable is being coiled on board during the operation of picking up, we may for a moment consider the approximate lengths of cable that can be stored in the tanks. It is not to be imagined that the whole of the tanks on board are ever completely filled with

* All rights reserved.

Digitized by Google

cable. Ships with four tanks could, as far as the amount of cable carried at one time is concerned, generally dispense with two; but the stowage of cable has to be regulated with regard to the trimming of the ship, and hence the total dead weight of cable is divided fairly evenly between the various tanks. While cable is being coiled on board ship from the manufactory or from reserve tanks on shore, the draught of water at the bows and stern is carefully watched, with the view of keeping the vessel in good trim. If too much is put into the aft tanks, and she is down by the stern, it will not be an easy matter to keep the vessel on her course under a beam wind or tide, the fore part of the ship being light. The tanks are usually not more than one-half or two-thirds full, the capacity of some ships being such that their tanks, if quite full, would hold enough armoured cable to sink them.

(To be continued.)

THE SUPPLY OF ELECTRICITY AT BRADFORD.

The Corporation of Bradford has been the first to municipalize the supply of electricity, and the undertaking has been highly successful. The local electric light work in this district was not remarkable either for quality or quantity, and it is chiefly to the exertions of Alderman Priestman that the town of Bradford owes the advantage of an electric supply.

The station presents no remarkable features or any novelties of particular interest to electric light engineers. It was started in 1889, and may be said to be representative of Messrs. Siemens' work, as the whole of the electrical plant is of their design and manufacture, and was erected by them. The Corporation is fortunate in having plenty of space, but the plant is compactly arranged, and can be considerably extended. There are six Willans sets and one Marshall. The first pair of Willans engines are coupled to Siemens dynamos in the usual way, and give a nominal output of 600 amperes at 150 volts at 285 revolutions per minute. The Marshall engine is inverted double acting, with cast-iron standard and wrought-iron pillars; it runs at 185 revolutions, and drives a dynamo giving the same output as those already mentioned. A very heavy and rather clumsy governor disfigures the appearance of this engine, which would be better suited for lower speed. Two triple Willans engines drive larger dynamos, giving 1,200 amperes at 300 and 350 revolutions, the volts being 150. Finally two small Willans-Siemens combinations give 300 amperes at 425 revolutions. These smaller sets are useful for day work and charging the batteries, but the diversity of sizes prevents the use of interchangeable armatures and other spare parts; while it does not appear to conduce in any material degree to better economy. The boilers, as might be expected in this part of the country, are of the Lancashire type, 7ft. diameter, 28ft. long, and supplying to the engines at 120lbs. pressure. The steam piping is not duplicated, and reliance is placed on branch and other stop valves for maintaining steam supply in case of a breakdown. A Babcock-Wilcox boiler is being set to assist in meeting sudden demands for current. A battery of Crompton-Howell cells of 1,000 ampere hours capacity and a normal discharge of 200 amperes was added to the station in 1891. A single discharge-switch is used in connection with it. The switch gear and cutouts, &c., are all of Siemens' design, some of the voltmeters are of the Schuckert type, and are used as indicators rather than voltmeters. A Thomson voltmeter is used as a standard for actually reading the volts. The main current is measured by the fall of volts over two sheets of platinoid, but as several large cables are connected along one edge the distribution of the current is of a very general character, and the result is not as trustworthy as that of an ordinary large ammeter.

The internal arrangements of the station being of the Siemens' type, it is natural that their armoured cable should be used in the streets, with the usual cast-iron joints and tees. For a permanent job nothing could be better, and, on the occasion of our visit, the insulation of the whole system, as shown by the usual pair of glow lamps, was excellent.

In a Paper read by Mr. Shoolbred, consulting electrical engineer to the Corporation, at the Society of Arts on Wednesday last, this type of conductor is praised as being thoroughly accessible. To get at any point, the pavement, six inches of earth, and a deal board have to be taken up; but the station being now fully loaded, the question of increasing the conductors has to be considered, and this will necessitate not only more copper, but new cables, and the taking up of the streets along the whole route. The cable is laid for the most part under the

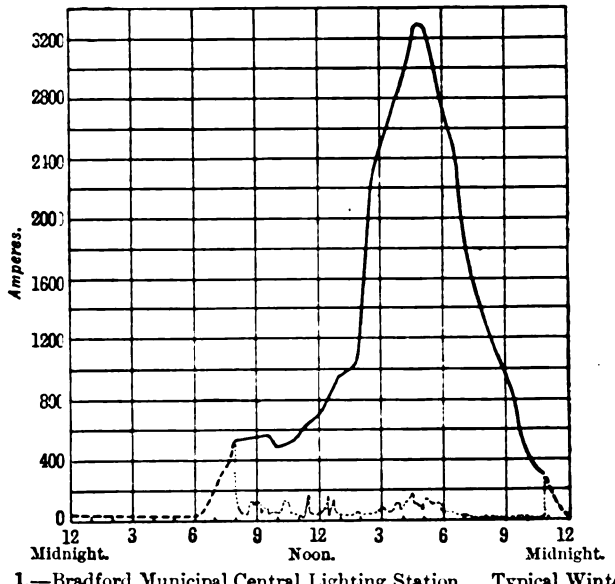

FIG. 1.—Bradford Municipal Central Lighting Station. Typical Winter Load Diagram, Dec. 23rd, 1891.

foot pavement. This, certainly, is the less expensive course; but when the whole has to be taken up for additions, it is a much greater nuisance than if the mains ran under the street. To take up the pavement is to make it practically useless for traffic, and shops and houses bordering on it are at a great disadvantage. The total length of mains is about 18 miles. The area includes a comparatively small part of the centre of the town.

The following diagrams are reproduced from Mr. Shoolbred's Paper:—Figs. 1 and 2 are winter and summer load diagrams. We have measured the load factors, and find them to be 0·282 and 0·153 respectively, taking the maximum output on each particular night as unity. The dotted lines represent the output of the battery. Figs. 3 and 4 show various costs and expenses during the last two years. Fig. 3 is not so valuable as it might be were information given as to the gradual increase of output; but we assume that this is fairly represented by the receipts.

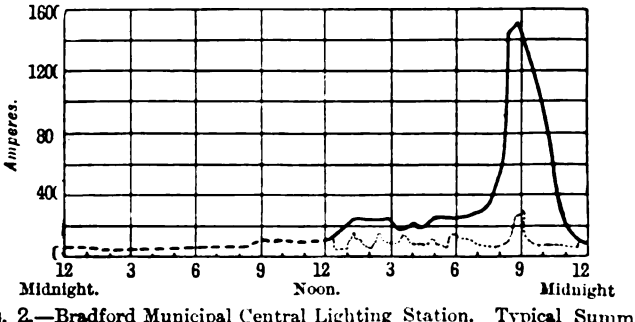

FIG. 2.—Bradford Municipal Central Lighting Station. Typical Summer Load Diagram, July 25th, 1891.

The Corporation is to be greatly congratulated on the continual decrease of the cost per unit, due, no doubt, to improvement in management under the able supervision of Mr Baynes, the introduction of feed-water heaters and economisers, which were not provided at first, as well as to the increased output. The fuel consists of "nuts" at 8s. to 10s. per ton, "slack" or coal dust at about half that price, and coke.

No reference is made in Mr. Shoolbred's Paper to the method of regulating the supply. We had been informed on more

Digitized by Google

than one authority that the standard pressure of 115 volts was not maintained with uniformity, but an inspection of recording voltmeter cards, and information given us by Mr. Baynes, the resident engineer, about lamp renewals, does not bear out this complaint. There are seven switch-boards, corresponding with

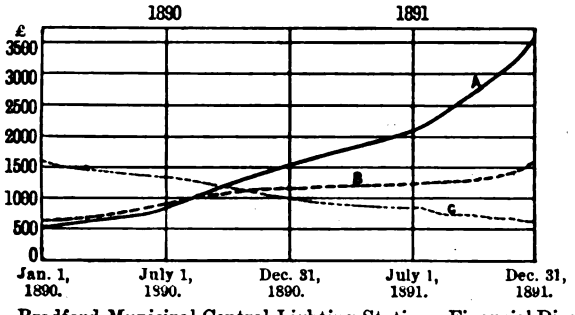

FIG. 3.—Bradford Municipal Central Lighting Station. Financial Diagram. A, total receipts. B, total expenditure. C, cost per unit.

the seven dynamos. One pole of each machine is joined to an omnibus bar; the connections of the other poles are kept on the other side of the station. A massive magnetic cut-out prevents the return of any current in case of the failure of a dynamo. Interlocking cam arrangements are provided on the switches. There are eight feeders, and the voltage at the station end at full load is about 125, the distant ends being maintained at 115, allowing nothing for distributing mains. The voltage of the dynamos is arranged to suit the highest voltage on any feeder, and resistances composed of wire rabbit netting

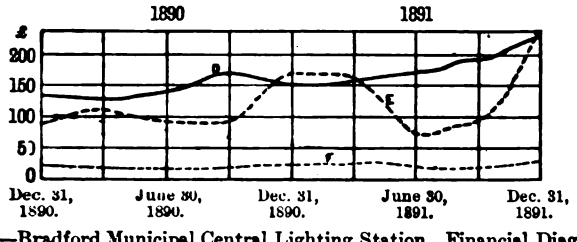

FIG. 4.—Bradford Municipal Central Lighting Station. Financial Diagram. D, wages, &c. E, coal. F, water.

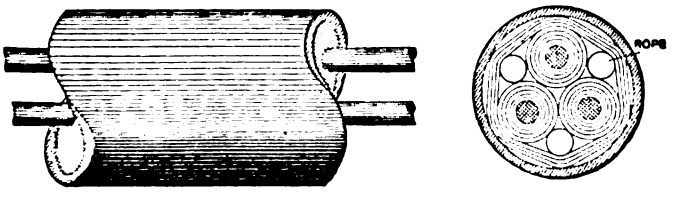
is introduced into the circuits of the other feeders to bring them down to the necessary pressure. We are informed that as there is but little residential lighting, the demand is so uniform that very little of this regulation is required, except on Saturdays. A considerable portion of the supply is under three years' contracts, and it is not until these expire that the real business can be estimated. Several motors of 4½ to 10 H.P. are in use for lifts and other intermittent work. With Willans and Marshall's engines, Siemens' dynamos, switch gear and mains, Crompton-Howell batteries, and a capable engineer, the station could not well be other than a success.

THE EDISON SYSTEM OF MAINS IN PHILADELPHIA.

The cable services of the Philadelphia Edison Company, says Mr. Israel in the *Electrical Engineer* of New York, should attract the attention of all electric companies maintaining an



underground system. The Edison Companies, particularly, should examine this means of reducing their expenses. The cable employed (*see* figure) consists of the three copper conductors of the desired diameters. The Philadelphia Company uses three sizes, of Nos. 41, 80 and 160, Edison Standard Gauge. They find these sizes available for all practical cases. Two services of 160 cable are used in places where an extraordinary load is to be carried. The conductors are separated by spiral windings of hemp rope, the space between being filled in with resin and cotton-seed oil. The rope braid is wrapped around the cable, and then it is encased in a one-eighth inch lead covering. The lead is painted with a waterproof paint. The resistance is very high, and the practical problem thus solved is simply to give the conductors more rope as insulation.

NOTICE.

With this week's number of "THE ELECTRICIAN" is issued (gratis) the Index to Vol. XXVIII. Complaints of non-receipt should be promptly addressed to the Publisher.

NOW READY.

Volume XXVIII. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad postage extra.

ALSO NOW READY.

Cases for binding Volume XXVIII., price 2/0, post free, 2/3.

The Publisher is now able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

BOOKS.

Some books, observes BACON, are to be tasted, others to be swallowed, and some few to be chewed and digested. Had he lived in our day he would have needs made a fourth class of those books which should be thrown away at once, or, better, burned. Was rubbish written in the days of BACON, or did he ignore it? *De minimis non curat lex.* If aimless and superfluous books on electricity came in driblets they could be disregarded; if in showers, they could be endured with resignation; but when they come in floods they seriously perplex the inquiring student, bewilder the intelligent public, and irritate the unhappy reviewer. Of the making of books, said KOHELETH, there is no end; and much study is a weariness of the flesh; but he probably knew no more about text books on electricity than good old BACON, who would have written a most interesting one if he had been given the chance.

The intelligent public ought, of course, to be, and is provided with more than one illustrated and readable description of the applications of electricity to the service of man in modern life. Such books ought not to be too large, for they are sure to become obsolete in a few years. A number of cheap handbooks have appeared on the bookstalls and elsewhere, generally designed to advertise the author or his wares; these appear to have met with some success, for new editions have been demanded. A new class of such books, called into existence by the spread of electric lighting, is addressed to consumers of electricity, who are presented with information about their lamps and the fittings which are connected with them, and the dynamo which generates the current, and the meter which measures it. Such books may, as BACON

Digitized by Google

says, be tasted. *De hoc multi multa, omnis aliquid, nemo satis.* One other kind of book has been provided for general readers, and as it is represented by a single work, and that one which can be thoroughly recommended, we do not hesitate to mention its name, "Electricity" and its authoress, E. M. Caillard.

Professors and schoolmasters are naturally tempted to make use of their lecture notes by expanding them into a book form; two such books at least have done excellent service, but are rapidly being made obsolete by the advance of science. Those teachers whose unhappy task it is to train their pupils to pass examinations, naturally spend their time on making cram books by which that object may be attained. No serious objection can be taken to cram books apart from the cram system. Any one who wants to get through a certain examination has only to look out for a crammer, and the crammer will give an estimate of his own ability in a numerical form, as a percentage of successful pupils and will recommend the books. Bacon's advice about these is, of course, that they must be swallowed.

Lastly we come to the highest class, and here we may pause. There are no floods or showers here; once in two or three years a valuable book is produced; one of the "some few to be chewed and digested." In this case the proportion between the number of books and the number of men who could write them is reversed; good books are scarce, though competent writers are numerous. It is easy enough to point out men who ought to write books, but they complain that they have no time. They contribute now and then to a learned society, and there are one or two volumes of their collected papers; but one man is overwhelmed with educational work and another with manufacturing business. The profits of authorship offer no inducement whatever, and thus good books are strangled. "As good almost kill a man," says Milton, "as kill a good book;" and is it too great a stretch of the imagination to suggest that the skeleton of a murdered book may be sheltered in many a scientific cupboard?

PACIFIC CABLE SCHEMES.

Almost ever since a submarine cable was successfully laid across the Atlantic projects have been from time to time brought forward for establishing a trans-Pacific cable. A map was issued over twenty years ago by Mr. Cyrus Field showing a projected route for cables from San Francisco to Honolulu, and thence northward to Japan and southward to the Australasian group. More than one company has been formed with the object of directly connecting America or Canada with Japan or Australia; but up to the present time not a single mile of these projected lines has been laid, and it is as difficult to say now when such connections will be made as it was twenty years ago. It is easy to understand why the Government and people of the United States should desire this direct connection, because (1) of their national jealousy of submarine cables being practically a British monopoly, (2) of the desire to have such a cable laid, believing that it would increase their trade with China and Japan, and (3) of the Government desire for diplomatic reasons to have direct communication under their own control with those countries. It is not, however, easy to see why there should be in this country such a strong interest in the laying of a Pacific cable. The principal reasons urged are, firstly, increased security of telegraphic communication with our dependencies in time of war, and, secondly, the belief that the existence of such a cable would have the effect of reducing the telegraph rate from this country to the Far East.

As to the first, nothing would be easier than to cut a single or even a duplicate line of cable under that vast stretch of water, which could not possibly be patrolled by our war ships with the view of protecting the cable lying beneath. As to affording increased security of communication in time of peace, it may be pointed out that on one occasion all three of the cables to Australia were simultaneously interrupted by earthquake, while quite recently communication with South Africa was cut off by the breakage of cables on the east and west coast of that continent at the same time. As to the second point, it is quite certain that even with large Government subsidies there could not be sufficient traffic to maintain a Pacific cable even at the tariff in force, under guarantee of the colonies with Australia, namely, 4s. per word.

The fact is that there is a certain sentimental charm about the idea of completely encircling the earth with cable, due, perhaps, in no small measure, to Shakespeare's expression about "putting a girdle round the earth in forty minutes." It is difficult to see any very tangible advantage at present to this country in such an extension of submarine cable enterprise unless an infinitesimally intermittent increase of the magnetism at the North Pole be considered one.

Sooner or later, however, the combined force of sentiment and increased trade will result in a Pacific cable being laid, and as the question is constantly being brought forward in Australia, Canada, and the United States, it may be of interest to examine the different routes which have been suggested. An important factor is, of course, the enormous depths which exist in the Pacific Ocean—one sounding of 4,655 fathoms (5¼ miles) being recorded on the charts, while in another instance the surveying vessel failed to get bottom with such sounding apparatus as she had on board. In another instance, to the South of the Friendly Islands, soundings of 4,430 and 4,295 fathoms have been found close to a shoal patch of 38 fathoms. Soundings of over 3,000 and even of 4,000 fathoms are common, and for great distances no soundings have been taken. The scheme which is being most persistently advocated is that of Mr. F. N. Gisborne, the Government Superintendent of Telegraphs of Canada. We publish a map which shows all the projected Pacific cables. The route recommended by Mr. Gisborne runs from Vancouver to Unimak Island (1,500 miles), thence *northward* of the Aleutian Group to Attu Island (800 miles), and on to Japan (1,300 miles). Total cable distance, with 12 per cent. of slack 4,032 miles.

The great objection to this route is the climate of the region through which the cable would have to pass. Mr. W. H. Dall, Acting Assistant U.S.C.S. in charge of Alaska Survey, who has had nine years' experience of the climate of this part of the world, and probably knows more about it than anyone else, makes the following remarks on the subject:—

"Except for their scientific value the explorations are almost thrown away. The two principal reasons why it seems inexpedient that a cable should be laid in that region, are the climate and the absence of any local demand for the use of the telegraph or opportunities for extension by branch lines.

"The climate is characterised by the almost constant prevalence of overcast, rainy, and foggy weather in the summer season, and of the most violent and sudden storms during the equinoctial periods and at irregular intervals during the winter. *It is the most foggy and stormy region in the world.* At all seasons cyclonic storms of the greatest violence occur, with but a few hours' notice at most! *I have never heard of any vessels seeing the sun in this region, and I doubt if there are three clear days in the whole year there.*"

Then Mr. Dall gives detailed accounts, showing that on 32½ days in the year a vessel might obtain her position, while on 332½ days she could not do so. The wind attains tremendous violence, and its speed was found to be 88 miles an hour. Such storms are frequent, and come on at 15 minutes' notice, and may last an hour or three days.

Laying aside the great difficulty and risk of laying a cable under such circumstances, no plan can be considered complete which does not include the consideration of facilities for repairs. Mr. Dall asserts that there are not over 30 days in the year when a vessel might be able to obtain her position close enough to take up and repair the cable at a given point; and that at least half this clear weather would be attended with so much wind that the work would be impracticable.

To this Mr. Gisborne, in a letter to us of March 22nd last, replies as follows:—

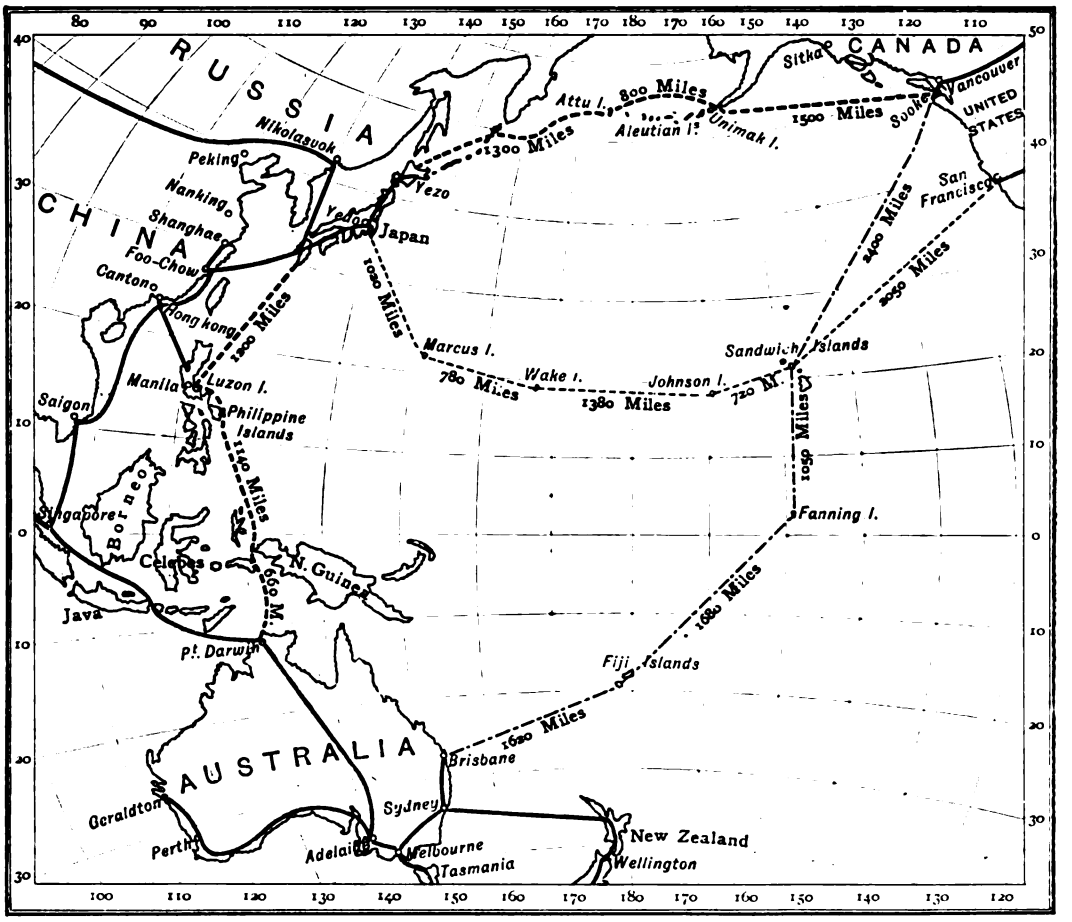
"In the first place—*vide* Admiralty Chart of the Pacific Ocean No. 2,683, 1887—you will note that the soundings between Vancouver Island

Digitized by Google

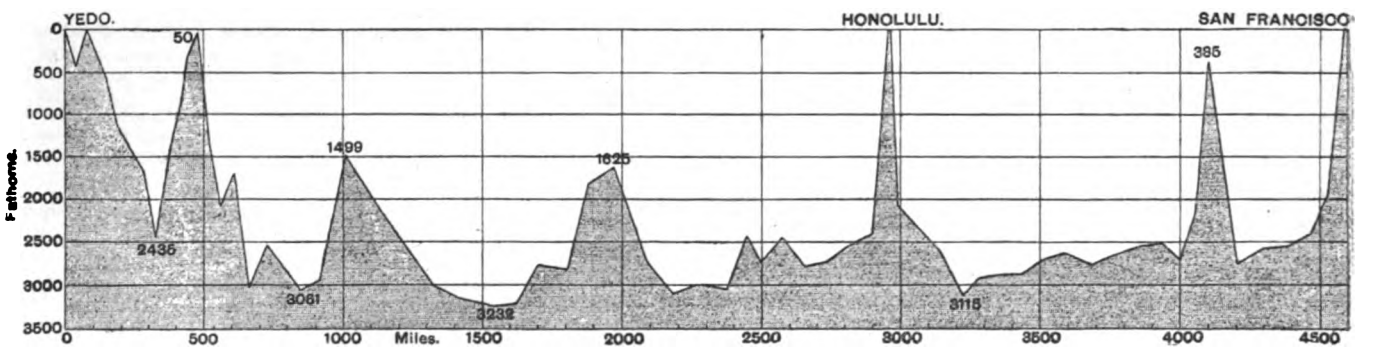
B.C., and Unimak Pass, Aleutian Islands, range from 2,000 to 2,500 fathoms, with as favourable a bed as the North Atlantic. That from Unimak Pass to Attu Island, north about (*vide* the U. S. Hydrographic Survey Chart of Behring Sea, No. 68), the maximum soundings are under 2,000 fathoms, with a favourable bottom. That from Attu Island to Kuril Straits (*vide* the Physical Chart of the World, Vol. I. of the Cruise of H.M.S. 'Challenger') the soundings are less than 3,000 fathoms, and are north of the 5,000 fathoms 'deep hollow' east of the Kuril and Japanese Islands. It was the 'deep hollow' on the direct line between the Sandwich and Japanese Islands which rendered the American project impracticable, and hence my amended possible route *vid* Johnson, Wake, and Marcus Islands, and my recommendation to the Imperial Government that they should take possession of them in like manner as Fanning and Christmas Islands had been annexed.

southern coasts of the Aleutian Islands in order to avoid the stormy weather of lower latitudes. November and March are the months of high winds, but the weather during the rest of the year is no more boisterous than the North Atlantic, although the rainfall is heavier.

"Thirdly, as to way traffic for cables. The distance between British Columbia and Japan is not greatly in excess of that between New York and England, and at Yezzo you are in direct communication with the four hundred millions of Japan and China *versus* the four millions of Australians *vid* the Sandwich Islands and Fiji Islands route, and be it remembered that *vid* Japan and Manilla Australia can be reached by 150 miles shorter lengths of cables than *vid* the southern route. I have no hesitation, therefore, in re-affirming my conviction that the northern route is the most feasible, and the only one that offers a reasonable prospect of becoming a commercial success."



Map showing the routes of the various projected Pacific Cables. (The figures give distances and not cable lengths.)



Section of bed of Pacific Ocean from San Francisco to Sandwich Islands, and thence to Japan. Vertical scale approximately 280 times greater than horizontal scale.

"Secondly, as to weather interferences with cable repairing. Mr. Dall's experience was during the coast survey of Alaska, with its densely foggy climate; but from Dr. George Dawson, F.R.S., one of our late Fur Seal Commissioners, who has lately returned from a three months' cruise throughout Behring Sea, I learn that although as a rule the sky was overcast they had no difficulty in obtaining observations or determining their exact position—that dense fogs do not occur as on the North Atlantic, and that when the sun is obscured the high peaks of the Aleutian Islands are nearly always available for the requirements of navigation. It is also notable that the steamers of the Canadian Pacific Railway take the northern route between Japan and British Columbia, and frequently sight the

As to Mr. Gisborne's comparison of the four hundred million of Japanese and Chinese with the four millions of Australians, in regard to telegraph traffic, a parody of Tennyson's line may be permitted—

"Better fifty men from Europe than a million in Cathay,"

as it is absolutely certain that not one in a million of the natives of Japan and China ever send a cable message, and the time will probably have to be reckoned in centuries before any considerable revenue is derived from this source.

Digitized by Google

Again, in regard to Mr. Gisborne's references to the soundings on his projected route, it must be pointed out that there are vast stretches over which the latest Admiralty charts show no soundings whatever, and this is particularly the case to the north of the Aleutian Islands. As, however, Mr. Gisborne produces some evidence controverting the report already referred to of Mr. Dall, it may be worth while to give the following extracts from the sailing directions for the North Pacific Ocean.

'*Aleutian Archipelago.*—The prevalence of fogs, the rapidity and uncertainty of prevailing tides, make an approach to any of the passes between the Aleutian Islands hazardous in the extreme."—Commander de Long, U.S.N.

'On all these islands traces of volcanic activity are evident. On many of them there are volcanoes in activity, and some, as for example Ounimak, are subject to continual volcanic eruptions and shocks.

"*Fox Islands.*—Rurick or Unimak Strait, through which Kotzebue passed in 1817, separates Unimak from the Krenitzen Isles to the southward. Its narrowest part is about 9½ miles broad. The currents are very violent in it, being variously stated to run at from three to six knots.

"*Kurile Islands and Strait.*—Kurile Strait, the passage between this Cape and Shumshu, the N.W. Kurile Island, is about eight miles broad, and very dangerous on account of the strong currents and the sunken rocks on either side, which narrow it to a width of three miles. The depth in this Strait is 10 to 20 fathoms, and from its east end a W.N.W course leads safely through.

"The name Kurile is derived from the Kamtchadale word for "smoke," the volcanic islands having been seen from Lopatka. The islands are all surrounded by fields of sea-weed. Our acquaintance with the configuration of the Kurile Islands may be considered as tolerably complete. This result was one of the most difficult problems in hydrography. The fog in which the group is constantly enveloped; the violent currents experienced in all the passages or straits separating them; the steepness of their coasts and the impossibility to anchor near the land, are such formidable obstacles that it tries to the utmost the patience and perseverance of the mariner to acquire any knowledge respecting them.

'The south-west anti-trade or passage winds, which occupy all the northern part of the ocean, will require still fewer words. It has all the general characteristics of the similar wind in the Atlantic, and perhaps is more persistent on the western side of the ocean. But here it is very much affected by the vast area of land it passes over, and reaching the ocean as a very dry and cold wind it has a correspondingly severe effect on the climates of the northern parts of Japan, Saghalin, the Sea of Okhotsk, &c., which are proverbially inclement, and for a long period of the year completely ice-bound.

"On reaching the open ocean, where the great return stream called the Japanese Current runs to the north-eastward, carrying with it the warmer water of the tropical latitudes, this cold and dry wind so condenses the warmer vapours which hang over the current that they are condensed into almost perpetual fogs. A similar and well-known region is found in the vicinity of the Banks of Newfoundland, but here these fogs extend far to the westward and envelope more or less continually the extensive ranges of the Kurile and Aleutian Islands. Dissolving these vapours, and acquiring further humidity and also increased temperature in its further progress to the eastward and north-eastward, it is found on the Alaska coasts as a warm, rain-bearing wind, which deposits its abundant moisture on the coasts and islands of that comparatively unfrequented region."

In the light of such statements from eminent authorities on the subject as are given above, there is, to say the least, very small probability of the northern route being chosen for a Pacific cable. It may further be said that there is no settled population in any of the Aleutian Islands, and that any revenue derivable from whalers or sealers telegraphing is not worth consideration, and there is no probability of an adequate subsidy being obtained from Japan.

As there are no islands available for stations in a direct line between either Vancouver or San Francisco and Japan, and as the distance from San Francisco to Yokohama (4,750 miles) is much too great for a single stretch of cable, the only other route worth considering is what is called the southern route—that is to say, from Vancouver or San Francisco to the Sandwich Islands, a distance of 2,400 and 2,050 miles respectively; thence to Johnson Island (720 miles), on to Wake Island (1,380 miles), Marcus Island (780), and up to Japan, 1,020 miles, a total of 6,000, or with 12 per cent. of slack, 6,500 miles; or from Sandwich Islands to Fanning Island, 1,050 miles; thence to the Fiji group, 1,680 miles; and on to Brisbane, 1,620 miles—a total of 6,750 miles. The above figures of the distances (not cable lengths) between the places named are Mr. Gisborne's, who, in his estimates, has allowed 12 per cent. for slack; but in view of the great depths of water at least 15 per cent. would be necessary. Almost all of the smaller islands in the Pacific available for intermediate stations are surrounded by belts of coral, so that the very greatest care would have to be taken in selecting landing places, otherwise the shore ends would be very quickly destroyed.

In view, however, of the fact that the Australasian colonies will probably eventually subsidise a Pacific cable, and that subventions might be obtained from Great Britain and France in respect of Fiji and New Caledonia, it is almost certain that the last route described will be the one ultimately adopted. In this case the cable distance, allowing 20 per cent. of slack, will be as nearly as possible 8,400 miles, and the cost, at £250 per mile, which is a low figure in view of the large core and large amount of gutta-percha necessary to get a moderate speed over such very long sections, would be somewhere in the neighbourhood of two millions sterling. It would certainly be necessary to maintain at least one ship to restore communication in the event of interruptions, at a cost per annum, say, of £15,000. There would be five stations costing, say, £2,000 a year each—total £10,000. In the case of a new company with so extended a stretch of cables laid in such great depths of water, 5 per cent. per annum should be set aside to provide for the renewal of the cables, at all events until a respectable reserve fund had been built up. This would require £100,000 per annum. Add to this £5,000 yearly for expenses of management, and we find that the working expenses and reserve would come to £130,000, while to pay a dividend of 5 per cent. a revenue of £230,000 would be necessary. Assuming—which is, however, assuming a great deal—that subsidies to the extent of £50,000 per annum for 20 years could be obtained from the various Governments interested, a revenue from cable messages of £180,000 would be required. As a matter of fact, assuming that all the Japan, China, and Australia traffic to Canada and the United States went by the proposed route, this would be very considerably more than the present revenue derived from that traffic. Mr. Henniker Heaton, in a Paper read before the Society of Arts in February, 1890, estimated that if a Pacific cable were laid traffic might profitably be carried from England, *vid* the Atlantic, North America, and the Pacific to Australia, at 1s. per word. It is only necessary to quote such a statement to show its absurdity. The present rate from England to America alone is 1s. per word. Assuming that the Pacific cable got, out of a shilling rate, 4d. per word, and carried ten paying words every minute of the year, the revenue would only be £87,600, whereas in practice the great bulk of the traffic has to be carried in eight or ten hours out of each twenty-four.

When some one told Canning that war was inevitable sooner or later, he replied, "In Heaven's name then let it be later," and his remark applies to a Pacific cable. The greater the time that is allowed for the opening up of China and Japan to commerce, and for the increase and multiplication of the Australasian population, the better will it be for the shareholders whose money is subscribed for this enterprise. This does not, however, apply to this extension being carried out by the existing companies, for obviously, with their large reserves and power of issuing debenture stock in a few years at 3½ or 3¾ per cent.—their existing Four per Cent. Stock being at a considerable premium—they are, or rather will be, in by far the most favourable position for handling the matter when the time to do so shall be judged to have come; while their great experience of cable-laying, and the use of their ships in taking a line of soundings for the cable, would be important factors in the durability of the cable, and would result in less frequent repairs or renewals.

NOTES ON THE LIGHT OF THE ELECTRIC ARC.*

BY ALEXANDER PELHAM TROTTER, B.A.

(Concluded from page 689.)

Two other kinds of arc are the lighthouse and the search-light. A very elaborate set of experiments was carried out in 1878 at Chatham under the direction of the Royal Engineers Committee, by Major R. Y. Armstrong, Lieutenant G. Bowker, Lieutenant P. Cardew, Lieutenant L. Darwin, Lieutenant G. A. Carr, assisted by Lieutenant R. White and Captain Abney. Ten dynamos, six lamps, six projectors, and five kinds of carbons were tested; photometric measurements were made, and photographs were taken

* Paper read April 28, 1892, before the Institution of Electrical Engineers.

Digitized by Google

both facing the crater and at right angles to it. From the photographs the area of the crater could be determined. The candle-power per square inch seemed to vary in an indefinite way between 76,000 and 25,000 candles per square inch.

The photographs taken from the side give a very good idea of the position of the carbons and the small obstruction of the negative carbon when a search-light is properly arranged. Finding that so complete an examination of search lights has been made, the author has not proceeded with the experiments which he had intended to carry out on this kind of lamp. He had some difficulty in finding this report, which was intended for Government use only. He was allowed by Major R. Ruch to examine a copy at the Horse Guards, and on making application through him to the Inspector-General of Fortifications the report was allowed to be made public. Instead of attempting to abstract this very interesting research, the author has presented the copy to the library of the Institution.

By permission of Mr. Inglis, secretary to the Trinity House, the author was permitted to examine the working of the St. Catherine's Point lighthouse at the beginning of the present month, and to have the machinery run during the daytime. The magneto-machines and lamps are the same that were used at the South Foreland in 1884 and 1885. Alternating currents from 180 to 300 amperes are used, the volts at the lamp are only about 35 to 38. Sir James Douglas's fluted carbons of 50mm. and 60mm. diameter, are used, the smaller size being employed during clear weather. Fig. 8 gives a section of one of these carbons full size; they have a graphite core. The conditions are altogether different from the continuous-current arc which has been described. It was found during the South Foreland experiments that a short arc gives more light than a long one. It must be remembered that the horizontal light is the most useful, although in a large lantern a considerable angle is utilised

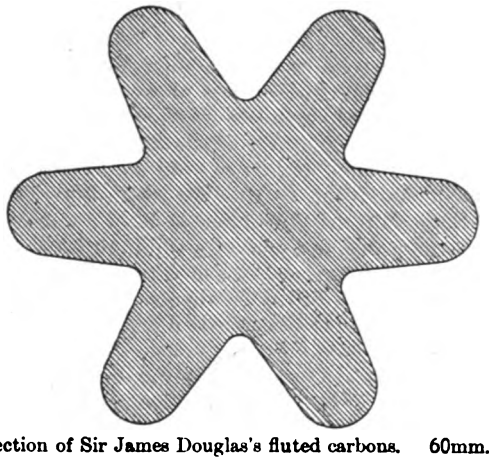


Fig. 8.—Section of Sir James Douglas's fluted carbons. 60mm. (full size).

by the lenses. A large alternate-current arc is very unsteady, the flame burns away the carbon in a very irregular manner, and when round carbons were used a hollow crater was formed at the end of each. The walls of the crater would give way, and cause great variation in the light. By the use of fluted carbons little, if any, hollowing takes place, and the light is more uniformly emitted. It seems probable that since each carbon is only at a high state of incandescence during half a period, that a short arc gives more light, because the carbons keep each other warm. The same amount of radiant energy may be given off with a long arc and a short one, but when the chilling of the negative is reduced a greater proportion of the radiation will be in the form of light. With a long alternating arc the flame wanders round, and is blown violently sideways, and the crater therefore tends to be shifted to one side of the carbon. The distance between the carbon is only $\frac{1}{16}$in. to $\frac{1}{8}$in., and as they are by no means flat it is the exception that any interval can be seen between them.

The author understood that an optical apparatus was provided for projecting the image of the arc on the side of the lantern, for the purpose of keeping the carbon points in the focal plane of the lenses. He found no such instrument was in use at St. Catherine's Point, but a very satisfactory image was thrown by the object glass of a telescope. The distances were arranged so that the image was full size. The shape changed so quickly that it was impossible to draw the image with great accuracy, and attention was paid only to the outline of the carbons and of the crater. The outlines in Fig. 9 are reproduced from a series of 12 tracings made at intervals of half a minute. Fig. 10 shows an irregular interlocking of the two carbons. This does not appear to have any connection with the flutings of the carbons, and the author has noticed it on several occasions, both at the lighthouse at the recent Naval Exhibition and at St. Catherine's Point. A glance at these tracings shows that only a very small portion of the true light-giving surface is visible, owing to the shortness of the arc.

The areas of the crater on the tracings was measured by a planimeter, the tracing point being taken ten times round. The mean area of Fig. 9 is 0·2087 sq. in., and the mean of Fig. 10 is 0·146 sq. in. The interlocking form of crater appears therefore to give about 30 per cent. less light. The candle power for 240 amperes, according to the measurements made at the South Foreland in 1884 and 1885, is about 16,000 c.p., giving about 75,000 candles per square inch if the light were entirely due to the crater. The area of the yellow and orange-coloured parts of the carbons was very difficult to estimate, but it was very much greater in proportion to the true crater than in a continuous-current lamp taking 10 to 20 amperes. Taking these parts as exposing about four times the area of the crater, and giving a one-eighth of the light per square inch, the crater alone may be taken as giving two-thirds of the whole, or about 50,000 candles to the square inch. This agrees fairly well with the result already given for the measurements at Finsbury.

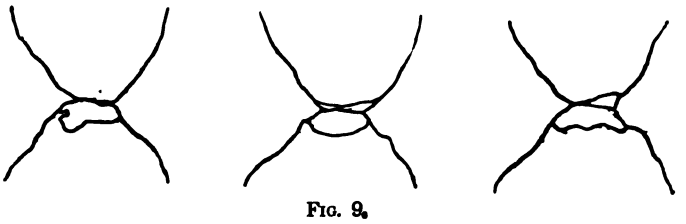

Fig. 9.

It was found, during the South Foreland experiment, that 40mm. cylindrical carbons became red hot throughout their whole length when 300 amperes were passing. The fluted carbons, measuring 60mm. over, have a sectional area equal to that of a cylinder about 46mm. diameter, that is $2\frac{1}{2}$ sq. in.; but the cooling surface is about 50 per cent. greater. Larger carbons would probably burn yet more irregularly, and yet it seems very desirable to increase the light during foggy weather. If the ends of the carbons could be maintained conical, all the light-giving surface would be usefully employed. A carbon which is more and more refractory towards the centre suggests itself; but even at present the consumption is from $1\frac{1}{2}$ to $2\frac{1}{2}$in. per hour, and modification can only be made in the direction of less refractory material. The flame might be made to spin round the carbons under the influence of a magnetic field; but the simplest plan seems to be the revolution or gyration of the carbons about a common axis, their centres being slightly displaced. In order to obviate sliding contacts, a gyratory motion would be the best. The power of the St. Catherine's Point Lighthouse has been called 6,000,000 to 7,000,000 c.p. This would require an area of crater of about 1 sq. ft.

The foregoing considerations about continuous-current arcs point to the value of a long arc, a small, and, if possible, a pointed negative carbon; but these must without hesitation be sacrificed to perfect steadiness. For outdoor work the uniformity of distribution is not much affected by the shadow of the lower carbon; indeed, it may, perhaps, be advantageous, for there is a fair amount of stray light immediately beneath an arc lamp; and if the lower carbon could be dispensed with there would be an overpowering illumination, which would make street lighting much more irregular than at present, unless very high posts were used. But for railway stations and for such places as the British Museum reading-room some improvements might be made in this direction. Experiments have

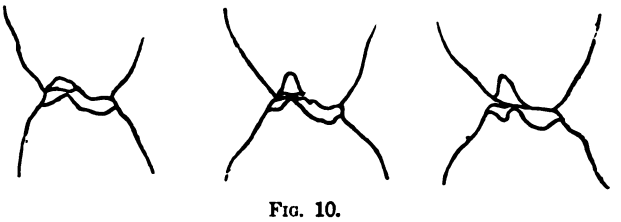

Fig. 10.

been made by W. S. Stanley (*Electrician*, Vol. XXVI., p. 646) with a carbon rod surrounded by a carbon tube arranged pointing downwards, and the arc has been made to travel round by magnetic rotation. The rod should be positive, as the end surface of the tube would be too large to keep incandescent unless with a very large current. The Jamin candle, a modification of the Jabochkoff, and the Rapieff and Hedges lamps, are examples of efforts in this direction.

[1] Several attempts have been made to improve the arc by adding volatile substances, or by introducing gas through a hollow carbon. The most successful of these appears to have been the Saunderson method of using hydrocarbon by means of a wick, but nothing has been heard of this for some time. The only good effect that can be expected is the production of a long arc which will reduce the shadow of the lower carbon; and it is likely that the temperature of the crater will be reduced by the presence of any substance less volatile than the best carbon.

Digitized by Google

With a scientific but misguided regard for truth, the candle-power of arc lamps has been reduced to its "mean spherical" value by many authorities. An easy way to arrive at this is to cut out a piece of card to the shape of a candle-power diagram, such as Figs. 1, 2 or 3. By balancing this on a pencil, on a line parallel with the perpendicular axis, the centre of gravity may be found. The area may be measured with a planimeter, or by comparing the weight of the card with that of the rectangle out of which it was cut, or by treating the curve as being composed of half an ellipse and part of a parabola.* Then, measuring the distance of the centre of gravity from the axis, and multiplying this by 2π times the area, the solid contents of the figure of revolution of the curve about its axis are obtained. The mean spherical candle-power of the arc is equal to the radius of a sphere, having the same solid contents. As so little light is emitted above the horizontal, it would seem quite as useful to take the mean hemispherical candle-power. But we not only learn nothing fresh, but are likely to be misled, for a light giving the same mean spherical candle-power would not be nearly so useful as an arc. The mean spherical candle-power has been found by M. Rousseau by plotting to rectangular co-ordinates.† But the method is not much easier, and it seems better to retain the polar curve, which has a geometrical meaning.

Since there is little or no difference in the light-giving properties of arc lamp carbons, the various qualities differing mainly in homogeneity and rate of burning, and since there must be a definite relation between the watts expended and the area of the crater or the candle-power, it seems preferable to denominate the size of arc lamps by the number of watts expended. There is no reason why the maximum candle-power at the best angle should not be given, if the candle-power be mentioned at all; but the carbons should be very carefully centred, and the test should be made, either with several photometers simultaneously, or with a lamp revolving like a meat jack. The nominal 2,000 candle-power, which 10-ampere arc lamps are sometimes supposed to give, is a perfectly unjustifiable convention, and has been very properly characterised as "a fine old crusted lie."

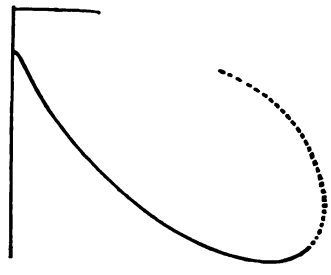

Fig. 12.

It might be imagined that, since an ordinary opal globe surrounding an arc lamp does not appear to differ greatly from a uniformly luminous sphere, the candle-power at different angles would be very much more uniform. This is not the case. Fig. 12 has been derived from the measurements of the illumination on the surface of the street by an arc lamp in Cornhill, an opal globe being used; the dotted line is assumed. Fig. 13 is a similar curve, derived from measurements made in Queen Victoria-street with arc lamps enclosed in moulded glass.

Owing to the difficulty of comparing the light from an arc lamp with the light of a candle, on account of the difference of colour, it has been a common practice to make photometric measurements with red and with green glasses, and elaborate tests have been made by Prof. Nicol and others throughout the whole range of the visible spectrum. The red and green glasses allow rather more definite readings to be made; but by a little practice with a photometer, which allows very free and rapid changes to be made by the oscillation of a lever or a handle, very much greater accuracy may be obtained than with an instrument in which a screen or a lens has to be moved on a slide until a balance is effected. But the green and red measurements having been taken, no one has yet suggested what is to be done with them; neither the mean, the sum, nor the product, has any physical meaning, and the two readings are generally given side by side. For purely scientific work, where the light is treated as radiant energy, either the whole spectrum should be measured and compared with a standard, or the luminous rays should be carefully separated from the dark heat rays, and the radiation measured as a whole. Such measurements have been made by H. Nakano and by Louis B. Marks,‡ and form a very valuable contribution to our knowledge of the efficiency of the arc.

* Area of ellipse = minor axis × major axis × $\pi/4$. Area of parabola = base × 2/3 height.

† Eric Gerard, "Leçons sur l'Électricité," Vol. II., p. 298.

‡ American Institute of Electrical Engineers, May 21, 1890. *Electrician*, Vol. XXV., p. 150.

It has been shown by M. A. Crova* that the portion of the spectrum lying near $\lambda = 582$ gives a true measure of the total candle-power of a light. Prof. E. L. Nichols† finds $\lambda = 600$ to be the position. For a considerable range of temperature the ratio between the different intensities of this part of the spectrum is practically identical with the ratio of the candle-power of two lights.

The use of the green and red measurements, besides facilitating the work of the photometrist, is to compare, in a rough way, the whiteness of the light under observation with a standard light. The measurements of M. de Nerville‡ afford some information as to the colour of the arc lamps at the Hippodrome, the glow lamps at the Opera House, and the gas lighting at the Post Office at Paris. But this information can be obtained only in the arbitrary terms of the ratio of the red reading to that taken with the green; when these two are equal, and the ratio is unity. This was the case with the Edison lamps at the Opera House, but it tells us nothing. A complete luminosity curve for each glass throughout the spectrum would be required to explain these readings; but even then the resultant luminosity curve could not be derived. Some idea of the quality of the light thus measured may be determined by comparing the ratio of the red and green components of some standard light. Such a comparison may be made with measurements made by M. de Nerville on the illumination produced by bright sunlight shining on a window with white blinds. The ratio of green to red in this particular photometer was about 3·5 to 1 for sunlight at four o'clock in the afternoon on May 1, 1890.

Captain Abney has made many investigations on the colour of daylight, and a chapter is devoted to this in his popular book on colour measurement and mixture. In searching for a standard light of uniform colour he found nothing to equal that which is given from the crater of an arc. This is very satisfactory to electrical engineers, but it gives no definite information as to the real quality or degree of whiteness of the light. The popular idea, and one which is very firmly fixed, is that arc lamps give a bluish light, sometimes rather violet, that it shews up certain colours in a sickly or unnatural manner; and there is a widespread belief that it not only acts injuriously on the complexion, but pierces cosmetic embellishments. These ideas are of so serious a nature that the

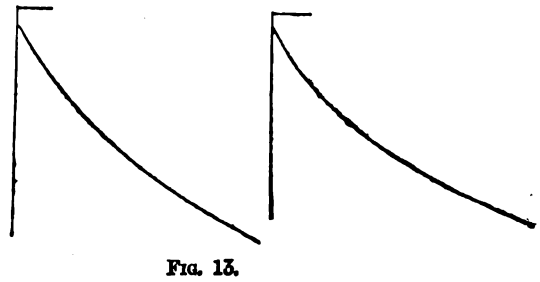

Fig. 13.

author ventures to discuss the quality of the light of the electric arc; since, although it is not a strictly electrical matter, it has a rather important aspect, in so far as it is a more or less unpopular feature of electric lighting.

The only standard of pure white light which we have is that of the diffused light of a summer day. Artists are familiar with the fact that direct sunlight is yellowish§, even on the clearest days; and that a blue sky, on the other hand, gives distinctly blue light, and that both of these must be avoided, or a picture painted under such lights will appear too cold or too warm when hung in a diffused light. Captain Abney has found that at different seasons of the year and at different times of the day very considerable changes occur in the colour of sunlight, owing to the absorption of bluish light by the atmosphere. It does not, however, appear impracticable to the author to fix on a fairly typical degree of whiteness, such as that of chalk, whiting, or alumina exposed to diffused light in summer time. A luminosity curve of the spectrum of such light would be a standard. Compared with such a white, or indeed by a very rough comparison with ordinary daylight in clear weather, the arc gives a distinctly pale primrose light, rather warmer than straw-yellow, and, to the author's eye, distinctly yellowish, in spite of the pale violet flame of the arc, which with inferior carbons occasionally flares up at irregular intervals. It is no use telling an unscientific person

§ Dr. W. J. Russell and Capt. Abney, on the other hand, say "The light from a sky which is cloudy has very much the same composition as sunlight itself, as we have repeatedly proved." "The proportion of blue rays in sunlight near mid-day in May is very nearly the same as the standard light" ("the white hot crater in the positive carbon pole of the electric light").—"Report on the Action of Light on Water-Colours," c. 5453 1888, pp. 23 and 69.

Digitized by Google

that the light is not blue but pale yellow; he will answer, "it appears to me to be blue or violet, and, therefore, to me and to ninety-nine people out of a hundred it *is* blue or violet."

Three reasons can be brought forward to explain this optical illusion. After dusk we are accustomed to the use of strongly yellow and even orange-coloured light of gas, lamps, candles, or glow lamps; and our own idea of whiteness is lowered. The whitest thing that we can see is a sheet of white paper, which is, of course, no whiter than the yellow light of the lamps; we imagine that it *is* white, and thus a false standard of white is obtained. When a really whiter, though not perfectly white, light is introduced, it naturally seems to be bluish compared with the false standard of white. Whether our idea of white really becomes altered is a psychological question which it would be out of place to discuss in the present Paper. Secondly, after dusk, the blue-seeing nervous elements of the eye (on the Young-Helmholtz theory) are allowed to rest, while most of the work falls upon the red and green-seeing elements. These latter become wearied, while the former are in a more highly receptive condition than during the day. As soon as a light containing a tolerable proportion of blue light is seen, it naturally appears to be more blue than white. The third suggestion is based upon a result of Captain Abney's researches, which show that for the most feeble illuminations no colour can be distinguished, and that the first colour which can be discovered is blue. He finds, and is supported in this by Lord Rayleigh, that the faintest light appears of a greyish-green colour, and Captain Abney attributes the apparent colour of moonlight to this cause. The author does not attach much importance to the application of this phenomenon as an explanation of the colour of the light of arcs, but it is worthy of record in this connection. When the eye passes gradually from daylight into electric light without seeing any distinctly yellow light, the sensation of blueness is rarely, if ever, observed.

It would be easy to humour this optical illusion, as is done at the British Museum reading-room, by the use of screens of yellowish glass; but a much more important consideration is the value of the arc light for the proper discrimination of colours; and though it is found in dye works that most colours can be matched with a good 15 or 20-ampere arc, there appears to be no reason why a perfect reproduction of a standard daylight quality of whiteness should not be obtained, at all events with arc lamps if not with glow lamps. The public would not be ready to believe it, they would call such a light bright blue; but that does not matter much. As the idea did not occur to the author until the autumn of last year, he has been unable to make experiments with summer daylight, but as it would be a misfortune if it were patented, he takes the present opportunity of describing the principle.

The full line in Fig. 14 is the luminosity curve for the light of the positive pole of an arc as determined by Captain Abney. The horizontal scale is the length of the spectrum, and the letters refer to the well-known lines. The ordinates are a measure of the brightness of each part of the spectrum. The dotted line is the luminosity curve for sunlight in May, from the same authority. Fig. 15 shows the difference between these two curves. The portions which lie below the horizontal line represent the excess of orange and greenish rays in the arc, and the portion which lies above the line represents the deficiency in blue rays. Such a deficiency has the same effect on the eye as an excess of yellow, and the whole effect is distinctly more yellow than sunlight. The light of a glow lamp at ordinary incandescence is almost exactly the same as that of gas. Fig. 16 gives the luminosity curves of arc and gas, and Fig. 17 shows the difference which, when the curve of gaslight is reduced so as to fall wholly within the arc curve, as in Fig. 16, consists of a deficiency which increases rapidly towards the blue.

Assuming ideal daylight to be rather less yellow—that is, more blue than sunlight, the dotted curves in Fig. 18 have been drawn from Capt. Abney's curves of sunlight and the light of blue sky. One-third of the difference between sunlight and blue sky has been added to the sunlight. The dotted curves are of the same kind, but the ordinates have been reduced. Fig. 19 shows the differences. Compared with the strongest daylight curve, the arc has a marked excess of orange, and a deficiency of greenish blue. With weaker daylight there is a greater excess of yellow, and with the weakest light shown, since it lies almost entirely within the arc curve, there is practically no deficiency in the blue.

There are two different ways in which this result may be practically used to produce artificial daylight. A glass or other medium may be tinted with stains or dyes, which will absorb the proper amount of yellow and red light, and the lamp may be surrounded by such a medium; or a reflecting screen may be painted with such a colour that this yellow light may be absorbed, and the white light alone may be reflected. Blue glass chimneys are used for microscope work, and are occasionally used for reading lamps with the view of giving a more agreeable light. The lowest curve but one in Fig. 19 has a small deficiency of greenish blue, this would affect the eye as a very faint yellowish tinge. If the excess of yellow in the rest of the spectrum could be corrected, a very close approximation to daylight would be attained. About one-third of the useful power of the light would have to be sacrificed. With gaslight or glow

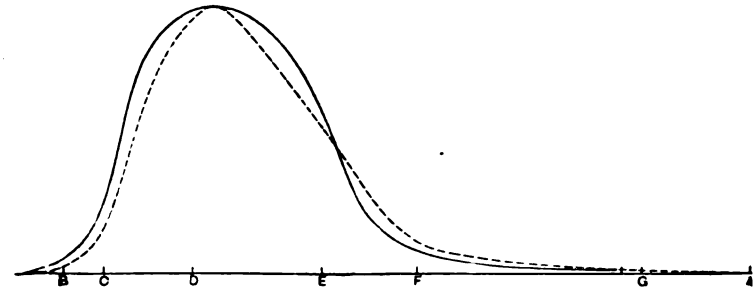

Fig. 14.—Arc and Sun.

lamps more than two-thirds of the light would have to be absorbed in order to reproduce the effect of daylight.

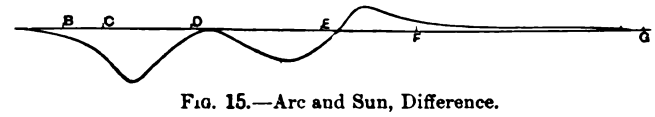

Fig. 15.—Arc and Sun, Difference.

Quite apart from considerations of colour-matching, the use of a white light ought to be good for the eyes, since all the nervous

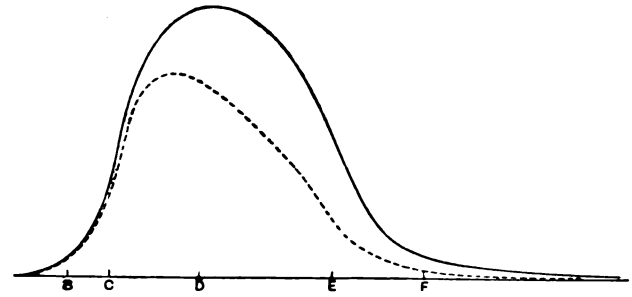

Fig. 16.—Arc and Gas.

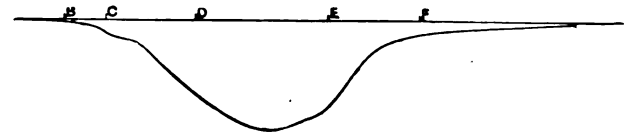

Fig. 17.—Arc and Gas, Difference.

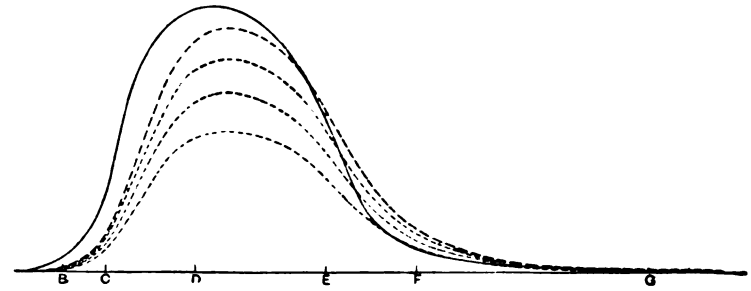

Fig. 18.—Arc and Daylight of Different Strengths.

elements would be equally excited as in normal daylight. The author has not yet completed his experiments on coloured shades,

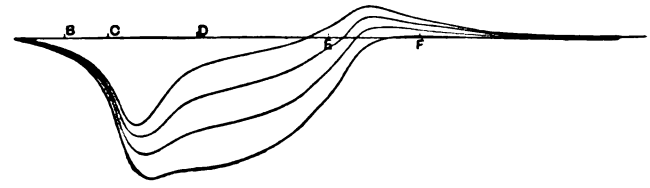

Fig. 19.—Arc and Daylight, Differences.

but has produced coloured screens which, when illuminated by lamplight, reflect a light which cannot be distinguished from white when compared with daylight. It does not follow that the light

Digitized by Google

is identical with daylight; but he hopes to follow up the matter during the summer.

The following measurements of red and green light from different sources have been made by Prof. L. Weber, of Breslau,* taking incandescent platinum as unity. Taking the Violle platinum unit at 18·5 standard candles, the author has converted them into candles per square inch and candles per square centimetre, and has added six other sets, with white light only, from his own observations.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 23, 1892.

The Electrical Control of Street Car Motors.—The methods of electrically controlling street car motors was the subject of a Paper read before the monthly meeting of the American Institute of Electrical Engineers last Tuesday evening by Mr. H. F. Parshall. While at first sight this appears to be a matter of secondary importance in street car work, it was pointed out that in reality it is one of the most important features to deal with, as the electrical design of the motor in no small degree depends upon the way in which its control is effected. Mr. Parshall's experience has been very extensive with a single class of motors, namely, the type using commutated fields. He has been connected with the Sprague and Edison companies for several years, and has had no small part in the designing of the motors that have been put upon the market by those companies. The particular advantages of the commutated field method were shown by Mr. Parshall to be that with a limited number of pounds of copper, or in the case of street car motors with a limited space available for field-magnet windings, it is possible to adjust the magnetising force of the field coils so that the rate of doing work of the motors may be made to correspond with the rate this work is required by the cars for various speeds and conditions of track. The precision with which this adjustment can be made depends upon the number of separate field-magnet coils, but the complications arising from using too many coils has shown that the practical limit is reached with about three separate spools on each limb of the field. It is the opinion of many practical street-car men that with even three coils the car winding is much too complicated for everyday use, as considerable trouble is experienced with the contacts.

The Thomson-Houston-Edison Consolidation.—It is announced this week that the Thomson-Houston Company has transferred the manufacture of its large power generators from its factory at Lynn, Mass., to the Edison Works at Schenectady, N.Y. This is one of the results of the recent consolidation of the two companies, and shows that, although there are two separate companies with distinct sets of officers, the management is really in the hands of a single individual. Mr. C. A. Coffin is generally credited with the virtual control of the entire business of the consolidated companies, and it is evident that the business of the two companies is being conducted along very different lines from what it was six months ago.

The Edison Filament Patent.—The Edison filament patent case was called last Tuesday in the Circuit Court of Appeals in this city, but owing to the non-appearance of one of the judges the case was postponed until Monday, the 25th inst. The case will be heard before Judges Lacombe and Shipman, and it is understood that both parties to the suit are ready with their respective sides of the case. Since the decision by Judge Wallace in the lower court, the consolidation of the Edison and Thomson-Houston companies has taken place, and this gives a somewhat different standing to the case from the point of view of the smaller manufacturers, since the interests of these two big concerns are now identical.

Telephone Patents.—The daily papers for the last few days have contained rumours of forthcoming important patents on the telephone. It seems that three patents will be issued by the U.S. Patent Office on May 3rd to Thomas A. Edison. These patents were assigned by Edison to the Western Union Telegraph Company, and this company in turn has disposed of its interest in the patents to the Bell Telephone Company. The patents are said to be fundamental in their nature, and to pertain to carbon transmitters. It is likely, however, that they have been in the Patent Office for a number of years, since it is well known that Edison has done no telephone work for a long time. The effect of the rumours on the Stock Market has been very marked, as Bell Telephone stock has very materially appreciated in value.

Electrical Literature.—A new book on power transmission is announced by a prominent publisher. The authors are W. M. Schlesinger and T. C. Martin. Mr. Schlesinger is at present connected with the Edison Company, and has had a wide experience in the transmission of power, especially for mining purposes; while Mr. Martin is well known as the present editor of the *Electrical Engineer*. Many American readers are looking forward with interest to the publication of this book on what is now the foremost topic in American electrical circles. I might mention here that the announcement of a work on electric traction by Mr. Reckenzaun, in England, has created considerable interest in this country.

GERMAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

On Thursday evening, April 17th, Mr. Ferranti visited the Cologne central station, and found the machinery, and especially the horizontal Sulzer engines which you illustrated in your issue of November 13, 1891, "very beautiful." On the whole he seems to have taken away with him a good impression of the station. Had he come about half an hour earlier he could have seen the 500 H.P. and the 125 H.P. running parallel for the purpose of switching the day load of the latter to the larger machine. During the recent bright and fine weather the consumption has been very small, and therefore the machines only run parallel when one is going to replace the other. It may be stated, however, that the engineer of the station, Herr Clarence Feldmann, ran the two 500 H.P. dynamos parallel for several nights, resistances being used to bring up the total load to 200 amperes and 2,000 volts. It is expected that the consumption will grow very fast in the autumn, and therefore a third 500 H.P. set has been ordered from the Helios Works and Gebrüder Sulzer, of Winterthur. Mr. Ferranti stated that he had not the least difficulty in running his machines parallel, even without any load, a fact which is not, perhaps, generally known, the reason he gave being that the machine was practically without any self-induction. Be this as it may, I know as a fact that the large alternators at Cologne and at Vienna run parallel to perfect satisfaction, and may be switched in or out without any fluctuation of the voltmeter, although these iron-cored Zipernowsky machines certainly have a good deal of self-induction. Mr. Ferranti admired the automatic regulator, the instantaneous action of which he could observe; and he was astonished to see the Bláthy 100-ampere meter start with one 16 c.p. lamp on. At present two 80-kilowatt dynamos are

* *Journal für Gasbeleuchtung, Electrician* Vol. XXV., p. 404.

Digitized by Google

at work. There is one interesting feature when the two large alternators are coupled in parallel. Looking at the magnet-wheel of one of them, you see the other magnet-wheel apparently standing still for some while, and then trying to move a little in one direction or the other, being kept in step by the controlling force that the two parallel machines exert upon one another. It is even possible to use this optical demonstration instead of the ordinary synchronisers. As soon as the two field-magnets seem to stand absolutely still, if you look at them in the direction of the shaft, the machines are in step, and the synchronisers will burn brightly, and the moment has come for coupling the machines in parallel.

The Frankfort civic authorities are becoming alive to the danger there is that many large electric light consumers will be supplied from block central stations. The site for the municipal central lighting station has been purchased, and the price paid shows that the situation is far from central; and whether the system ultimately adopted be the alternate or the continuous current, it will be a hard job to earn anything on the money that this station has swallowed already. Trials have been made costing thousands of pounds, experts have been consulted for year after year, schemes have been worked out by the dozen, and the Exhibition must also be counted as a costly item; it is certain that it would not have had such a success had the central-station contract been settled *before* its opening.

At the Electrotechnischer Verein of Berlin Herr Friedr. Ross lately read a Paper upon the cost and profits of central stations, in which he made some valuable proposals. The first of his proposals was similar to that of Mr. Crompton, namely, a regular exchange of data and opinions by central-station managers all over the world. At Düsseldorff Herr Ross stated that there had been an outlay of 840,000 marks on the plant for 13,000 to 14,000 lamps, or 60 to 64 marks per lamp. At Cologne, with 1,114,000 marks for 20,000 lamps, the figure is 57 marks. At Berlin it may be taken at 40 marks per lamp. These figures do not include the cost of the real estate, which was 5,700,000 marks at Berlin, and 600,000 marks in the case of the small station at Hamburg. For large stations on the outskirts of a town the cost of the generating plant may be taken at 50 marks per lamp, or about 1 mark per watt. The mains have cost 1,270,000 at Düsseldorff and 620,000 marks at Cologne, or 63·5 marks and 31 marks respectively, for each of the 20,000 lamps for which both these systems are calculated. These numbers include the house connections, and in the last case also the transformers. At Berlin the cost of the mains per lamp connected may be set down at quite 100 marks. According to Herr Ross the real cost of working for sufficiently large stations may be taken as 0·4 pfennig for administration, 0·25 pfennig for repairs and renewals, and 0·85 pfennig for current production, in all 1·5 pfennig for a unit of 50 watt hours (3d. per B.T.U.). Taking the high number of 1,000 burning hours per annum, Herr Ross pointed out that the total outlay is—

1. The real working cost for 50 watt-hours.....	1·5	pfennig
2. Interest and depreciation 10 per cent. of 50 marks for 1,000 hours.....	0·5	,,
3. Profit on the 50 watt-hour unit	0·5	,,
	2·5	pfennigs

leaving, at the assumed selling price of 3·5 pfennigs for the 50 watt-hour unit, an outlay of 1 pfennig for the mains, which, capitalised for 1,000 hours at 10 per cent., gives 100 marks, a figure which has so far only been reached by a few stations. It must be kept in mind that these 100 marks per 50-watt lamp have to include the house connections, and that a street length of 3·2 metres must be reckoned per 50-watt lamp connected, thus leaving a sum of less than 25 marks per running metre of useful street front. Herr Ross then proceeded to express a pessimistic view as to the future of electric motors as a means of increasing the earnings of a central station. He calculates that one H.P.H. may be sold at 8 pfennigs by the gas companies, and that an E.H.P.H. would cost 31 pfennigs. This latter figure seems somewhat extravagant, as the Berlin central stations sell the H.P.H. at 15 pfennigs.

The alternate-current central station belonging to the International Electricitäts Gesellschaft at Vienna has increased rapidly. It started in November, 1890, with a normal load of 524 kilowatts; on January 1, 1892, the load was 1,378 kilowatts. Each lamp connected is burnt on an average 780 hours per annum. The alternators were made by Ganz and Co., of Budapest, the engines by the Brünner Fabrik, and the boilers are, I believe, of the Babcock-Wilcox type. As at Cologne, the alternators are run in parallel. The cables were manufactured at Jacottet by the Austrian house of Messrs. Berthoud and Borel, of Cortaillod, who furnished the cables for Cologne.

At Cologne some very interesting experiments have been made lately with the telephone cable, which is laid next to the electric light cables. There was not the least "humming" to be heard, even when the two telephone wires were connected to one battery pole, the other pole being connected to earth.

It may be interesting to state that the German Elmore Company have erected large works at Schladem, near Cologne.

CORRESPONDENCE.

"ON THE RETARDATION DUE TO IRON PIPES."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am sorry to have to admit that I quite forgot Prof. Hughes' work in this direction, but his letter is so interesting that perhaps you will insert it, together with an extract from his paper.—Yours, &c., W. H. PREECE.

G.P.O., May 2, 1892.

"DEAR PREECE: I notice in *The Electrician* of April 29th your Paper on "The Retardation Due to Iron Pipes," and as I take an interest in this subject I should like to point out to you a few of the experiments I have already made on this subject, which certainly agrees with the views you have expressed.

In 1866 I read a Paper to the Institution of Electrical Engineers on "The Self-Induction of Electric Currents," which was published in their journal, No. 60. You will find there, page 95, that I showed the remarkable diminution of the self-induction of an iron wire by coating its exterior with a copper sheath. The compound wire tried was one given me by yourself, and I believe was the invention of Prof. Moses G. Farmer, of the United States.

Again, a still more remarkable increase of self-induction was shown by a copper internal wire coated externally with iron. This was also given to me by yourself.

The greatest increase of all, however, was shown when an insulated copper wire was placed in an external iron tube, the effects of which was fully equal to those you mention as being later observed in actual practice by Gen. Webber. Page 98 gives a table of comparative results, with and without an iron tube.

Again, in a Paper read before the Royal Society, May 24th, 1866, which I enclose, you will find under the title of "Influence of a Magnetic Sheath," page 463 to 466, a full research into this most interesting point. This shows that an iron tube surrounding an insulated copper wire conveying an interrupted or alternating current has the effect of increasing the apparent resistance of the copper wire seven times its value in the steady period, by the self-induction, or really the production, of circular magnetism in the outer sheath of iron.

You will notice that these effects are due primarily to closed circular magnetic circuits, as can easily take place in a tube, but which cannot so well be formed in a submarine cable, as then the mere separation of the wires prevents a perfect closed system of circular magnetism, and the retardation or diminution of the current is a mere fraction of what it would have been if it had been enclosed in a solid iron tube.

These experiments were made on short lengths, and the results I then obtained have all been since verified in practice, except my results with the iron tubes, so I naturally feel interested in your letter, which again proves that my results were correct, although at the time my method and results were severely criticised by Prof. Weber of Zurich. As I could not then prove the truth of my results by actual practice on long lines, I shall be very glad if you can continue your experiments on this subject and publish the results.—Sincerely yours, D. E. HUGHES.

W. H. Preece, Esq., F.R.S.
40, Langham-street, W.
May 2, 1892."

[Prof. Hughes' Paper was read before the Royal Society on May 27, 1886, and was reprinted in full in *The Electrician*, Vol. XVII., page 71, *et seq.* The passage referring to the influence of "Circular Magnetism," will be found on page 95, and to a "Magnetic Sheath" on page 118.—ED. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the very interesting particulars in your last week's issue of the effect of placing cables carrying alternating currents in iron pipes (each cable in a separate pipe), most electric light engineers who have had to deal with alternating currents were, no doubt, aware that there would

Digitized by Google

be a choking effect, but I think that but few would have anticipated so large a fall of potential as was observed by General Webber in the case in question. The remedy indicated by Prof. Ewing, viz., drawing the two cables into one pipe, is, of course, universally practised. In view of the probable development of the alternate-current transformer sub-station system of distribution with a low-tension three-wire network, it would be interesting to know if there would be any similar losses if the *three* wires were in one pipe or iron conduit. May I venture to ask Prof. Ewing if he will be good enough to give your readers some information on this point, and so add one more obligation to the many which we already owe him?—Yours, &c., H. W. W.

"THE KELVIN."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As you are doubtless already aware, the Board of Trade has added one more name to the terms commonly used in electric lighting. We have for some years been accustomed to speak of Board of Trade "units"; we must, in the future, speak only of Board of Trade "kelvins."

No doubt honour is due to Lord Kelvin, and it is an old saying that honour should be given to those to whom honour is due; but it is very doubtful whether the change will add to the reputation or popularity of the President of the Royal Society.

It has long been a question whether many of the terms used in electric lighting do not tend to confuse rather than to assist. The science is not easy, and it does not add to the facility for education that the terms used should have no relevance whatever to the meanings assigned to them.

In a recent case we had an inquiry from the learned judge—whose great ability is shown by the manner he mastered the difficulties of a difficult case—how the word "ampere" was spelt, and whether it was the same thing as a volt. It does not seem that the necessity for such an inquiry reflected well upon an industry the great claim for which is light, and it does not seem to be wise, therefore, that if changes must take place, they should be in the direction of greater complication.

Everyone can guess at the approximate meaning of a "unit," but even the most learned philosopher would be unable to make a guess at the meaning of "kelvin" unless he had read a Board of Trade Provisional Order.

In these days of democracy it has been the experience of those responsible for electric lighting central stations to find customers in the smallest houses and amongst the least educated people; but if the industry is to be carried on in the language of capitals and proper names it will soon become necessary for each supply company to engage a special staff of interpreters to explain the meaning of its measurements to proposed customers.

It is already becoming a fact that the establishment charges of a supply station are equal to the cost of generation; and if these charges are to be increased in this manner the small chance of profit to the investors will rapidly disappear.

Just imagine what would happen if—

A battery were called	"A Swinburne."
A transformer	"A Webber."
An earth return.....	"A Crompton."
A switch	"A Lane Fox."
A meter	"A Hopkinson."
A dynamo	"An Aron."
The three-wire system.....	"The Eustace Balfour."
A high-tension current.....	"A Kennedy," and
A low-tension current	"A Ferranti."

Surely such a nomenclature would create confusion, even in the minds of those who heretofore had been supposed to know most about electricity. And yet this is, it would appear, what things are coming to.—Yours, &c., M.

[Owing to great pressure on our space we have been compelled to hold over a portion of our Correspondence until next week.—ED. *E.*]

TRADE NOTES AND NOTICES.

TENDERS INVITED.—The Corporation of Hull are prepared to receive tenders for supplying and erecting wrought-iron steam, water, drain, and blow-off pipes, cast-iron exhaust pipes and tank, pumps, injectors, &c. Drawings and specifications may be inspected at the borough electrical engineer's office, Central Police Station, Hull; and sealed tenders, endorsed "Tender for Steam Pipes, &c.," are to be addressed to the Chairman of the Electric Light Committee, and delivered at the town clerk's office, Town Hall, Hull, not later than Wednesday, the 18th inst. Further particulars appear in our advertisement columns.

——— It will be seen by our advertisement columns that the Corporation of the City of Liverpool invite tenders for the execution of certain electrical work, consisting of wires and instruments for about 95 miles of telephone communication, with alarm bells and other electrical appliances required between Liverpool and Lake Vyrnwy, and between Liverpool and Rivington. Tenders must be addressed "The Town Clerk, Municipal Buildings, Liverpool," and delivered before 12 noon on Tuesday, June 7th.

——— The Corporation of Blackpool are prepared to receive tenders for the right of user for a period of seven years (with provision as to conditional renewal) of certain tramways constructed and authorised under the Blackpool Corporation Tramways Order, 1884. Tenders to be delivered to Mr. T. Loftos, town clerk, before 12 noon on Saturday, June 25th. Further particulars appear in our advertisement columns.

——— The Directors of the Yorkshire House-to-House Electricity Company (Limited) invite tenders for the supply and erection of the necessary machinery, &c., for a central supply station, and for providing and laying underground mains. Further particulars will be found in our advertisement columns. Tenders must be in by 11 a.m. on Thursday, the 26th inst.

——— The Corporation of Dublin are prepared to receive tenders for the supply of wires, fittings, and sundries, and the erection of the same for the electric lighting of some of the civic buildings.

TENDERS ACCEPTED.—The Metropolitan Asylums Board have accepted the offer of the General Post Office to provide and maintain telephonic communication between the western ambulance station and the administrative block of the adjoining hospital, at a rental of £5. 15s. per annum.

TENDERS RECEIVED.—At a meeting of the Bideford Town Council on Wednesday it was reported that only one tender had been received for lighting the town by electricity, which was from Messrs. Tardrew and Son, who estimated the cost of laying down dynamos, engines, wires (underground), cost of lamps, and of everything connected with providing plants and starting works at the Manor Wharf, at £4,680; and that the annual cost of supplying all the public lights of the town—and 505 other lomps if necessary—would be £620 per annum. The offer was referred to a committee to report upon.

MR. JULIUS SAX.—The Markets Committee of the City Corporation have, it is stated, granted a concession for 21 years to Mr. Julius Sax for the electric lighting at the Central Market, West Smithfield, London, E.C., Mr. Sax having undertaken the public lighting of the market free of charge.

DISSOLUTION OF PARTNERSHIP.—Messrs. Stanley and Dawkins, electricians, 80, Buckingham-street, Birmingham. Debts paid by W. A. Dawkins, who continues the business.

BANKRUPTCY.—Tuesday night's *Gazette* contains a notice of the bankruptcy of J. Slater Lewis, described as an electrical appliance manufacturer's manager.

DOMESTIC ELECTRICITY.—The display of domestic electrical appliances on view at the Crystal Palace Exhibition has, we learn, become quite a feature, and is much appreciated by the public. New apparatus has recently been added, and the lecture given twice each day by Mr. H. J. Dowsing is always largely attended. We learn that the success of this show has led to an order being given to Messrs. Crompton and Co. and the General Electric Company to supply a similar exhibit for the forthcoming International Horticultural Exhibition at Earl's Court, London. This is well worthy of still further extension, and we have no doubt that similar shows will be on view at future exhibitions throughout the country.

ELECTRIC LAUNCH AT THE CRYSTAL PALACE EXHIBITION.—Messrs. Woodhouse and Rawson have lately added to their stand at the Crystal Palace an electric launch. The "Lily" is 28ft. long, has a beam of 5ft. 6in., a depth of 2ft. 10in., and a drught of 2ft. The boat is built of mahogany, the sides being carvel with American elm keel and timbers, and has an oak stem, stern post and dead wood. The electrical equipment consists of a 2-H.P. "W. and R." motor, supplied wiih current from 30 "Epstein" cells. The weight of the launch complete is 25 cwt. She can accommodate from 12 to 15 passengers, and with one

Digitized by Google

charging (which occupies about four hours) will run seven miles an hour for five hours.

COUNTRY HOUSE LIGHTING.—"Lawnhurst," which is being built by Mr. Henry Simon at Didsbury, is to be lit electrically by Messrs. Drake and Gorham. Two Crossley gas engines will supply the power, and the current will also be used for driving a workshop, blowing an organ, and other purposes.

MESSRS. SIEMENS BROS. AND CO'S. WORKS.—The *Manufacturers', Engineering, and Export Journal* for April contains a very full and well illustrated description of the above firm's various works.

ISLE OF MAN INTERNATIONAL EXHIBITION.—An illustrated prospectus relating to this Exhibition has been issued this week, accompanied by a form of application for space, at the back of which are the instructions and regulations of the Exhibition. All further information can be obtained of Mr. Henry W. Pearson, General Manager, at the Exhibition Offices, Belle Vue, Douglas, Isle of Man, or of Mr. George North, of 90, Queen-street, Cheapside, E.C., representative in London for the Exhibition Commissioners.

"TELEPHONES: THEIR CONNECTIONS AND CIRCUITS."—Messrs. G. and M. Binswanger, of the General Electric Company, have just published a handy treatise on the above subject. The little book is fully illustrated, and the instructions given to those wishing to instal the telephone are full enough to enable anyone with an elementary knowledge of electrical apparatus to effect their object without outside assistance. Probably, with the exception of electric bells, the installation of the telephone most appeals to the ingenuity of the novice, and he should certainly find this *bro hure* of considerable use to him.

NATIONAL TELEPHONE COMPANY (LIMITED).—This Company notify their subscribers that on and after May 1st inst. a charge of 6d. will be made for the use of the trunk line between London and Brighton for each conversation of three minutes' duration, the charge to non-subscribers being double that rate. There is a six minutes' limit, and subscribers wishing to use the line have to enter into an agreement with the Company on a form which can be obtained on application.

ASSOCIATION FOR THE PROTECTION OF TELEPHONE SUBSCRIBERS.—A circular has been issued, notifying that this Association has been registered under the Companies' Acts, which information was given in our issue of April 18th last. It is stated that the Committee of the Association have satisfied themselves that the double-wire system adopted by the New Telephone Company is, in all respects, a great improvement upon the existing system. There is nothing in the circular to show how this conclusion has been arrived at, except that the National Telephone Company has not taken the Association seriously, and the New Telephone Company appears to have done so; in fact, it is evident that the Association has gone over, body and soul, to the New Company. Under the circumstances, telephone subscribers are, we fear, not likely to reap much benefit from the Association. At a small meeting held yesterday at the Cannon-street Hotel, it was unanimously decided to confirm an agreement with the New Telephone Company, conferring certain privileges with regard to the use of the Company's telephones upon members of the Association.

POSTAL AND TELEGRAPHIC REFORMS.—A draft letter is being prepared for signature to the Postmaster-General, with the object of inducing him to take into consideration a number of proposed reforms in his department. The petitioners represent an influential body of newspaper proprietors and managers, but the objects of the petition have a wider significance. These are (for the present) 17 in number, and are as follows:—(1) That all surplus of revenue over expenditure in the Post and Telegraph Department shall be at the sole disposal of the Postmaster-General, for the purpose of instituting Postal and Telegraphic reforms, and to be subject to no control by the Treasury Department, until such reforms have been effected, when the surplus is to be handed over to the Chancellor of the Exchequer. (2) That the postage on periodicals shall be uniformly one-halfpenny per copy. (3) Relates to the proportion of advertisements to news matter. (4) The hour of collection to be stamped on all postal packets. (5) The public to be allowed to transmit ordinary cards (official size) as postcards by the use of adhesive stamps. (6) Postcards to be sold at the face value. (7) The public to be supplied with double postcards, to be used for message and reply; these to be termed "Query" postcards. (8) A cash-on-delivery post to be established in this country, so that a Parcel Post official shall collect the money due upon the parcels he delivers. (9) Type-written and similar circulars to be transmissible at the book-post rate. (10) The establishment of an agricultural parcel post at an average charge of 1d. per lb. (11) The reduction in the case of inland parcels to a minimum of 3lb. for 3d, and a penny for every additional pound. (12) The issue of small money orders payable either at home or in our colonies. (13) The collection by the postal authorities of not more than the deficiency on any insufficiently stamped letter; this is in place of double the deficiency now collected. (14) All compound names of places in telegrams to be charged as one word. (15) The abolition of charges for porterage on telegrams, or at least a reduction of the charge to a sum proportionate to the wages of the messenger, which in the petition is put down at a penny per mile. In addition, the number of telegraph stations in country districts to be largely increased. (16) The adoption of the Indian system of sending cash with a telegraphic money order to the residence of the addressee. (17) Telegrams to be forwarded to France, Belgium, Germany, Canada, and the United States at 1d. per word; to India for 6d., and to Australia for 1s. per word. The existing cable systems to be purchased by the Government at a fair valuation. It will be seen that this imposing list of reforms loses nothing by being sponsored by newspaper proprietors.

COMPANIES' MEETINGS & REPORTS.

Eastern Extension, Australasia, and China Telegraph Company (Limited).

The thirty-seventh ordinary general meeting of this Company was held on Wednesday, at Winchester House, Old Broad-street; Sir John Pender, K.C.M.G., presiding.

The SECRETARY (Mr. F. E. Hesse) read the notice convening the meeting and the minutes of the last meeting, which were approved by the present meeting, and signed by the Chairman as correct. The report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, I shall, as usual, go over the accounts in detail, and if any shareholder should have any questions to put to me afterwards, I shall be only too pleased to answer him. The gross receipts for the half-year under review have amounted to £245,658, against £279,095 for the corresponding period of 1890, showing a decrease of £35,437, of which nearly £12,000 is due to fluctuations in exchange, £14,000 to the reduced rates to Australia, to which I shall presently refer in greater detail, and the balance to the commercial depression which has prevailed in the Far East for some time past. The working expenses have been practically the same as during the corresponding half-year of 1890. Comparing the figures for the whole year the results are as follows:—The gross receipts for 1891 were £508,536, against £533,951 in 1890, or a decrease of £25,415. The working expenses for 1891 were £145,790, against £150,760 in 1890, or a decrease of £4,970. The net revenue for 1891 was £289,522, against £303,482, or a net decrease for the year of £13,960. The usual interim dividends have been distributed during the past year, making the dividend proposed to be paid to-morrow a total dividend of 5 per cent. for the year. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the past year. The balance of £111,987 has been carried to the general reserve fund, which now stands at £428,842, made up as follows:—Amount of fund at end of 1890, £495,239; interest on investments during year, £15,129; profit on sale of investments, £1,424; and balance from revenue, £111,987, making a total of £623,779, less £144,135 charged against reserve during the year for balance of cost of Madras-Penang (Duplicate) Cable; also £35,878, for balance of cost of partial renewal of Hong Kong-Tonquin and Madras-Penang (Original) Cables; and £14,924 for cost of Penang-Sumatra cable, leaving the fund, as already stated, at £428,842. Since the amalgamation in 1873 we have spent out of revenue and reserve in cable renewals and duplications, £1,153,736. If that sum had not been spent I doubt if you would be receiving the dividend we are about to pay, and I am quite sure that our Company would not occupy the very proud position that it does to-day, for you have got your cables duplicated and some sections triplicated, you have not had your capital increased, and your dividend has been maintained. A further drawing of 337 of the Company's Five per Cent. Australian Subsidy Debentures took place on the 4th ultimo for payment at par on July 1st next, when the Debenture Debt, which originally stood at £640,000, will be reduced to £320,000. With regard to the reduced rates to Australia, which is a very important question, I may mention that since the report was issued to the shareholders we have completed another month's working under the guarantee arrangement made with certain of the Australasian Governments for testing the effect of a 4s. rate to Australia, and we are consequently in a position to give the figures for the full year of experiment. The number of words transmitted during the year has increased 50 per cent. over the corresponding period of 1890-1891, and 61½ per cent. over that of 1889, the year adopted as the basis of the "guarantee," while the receipts have diminished to the extent of £55,040. As you are aware, one half of this loss, or £27,520, is borne by the guaranteeing colonies, divided as follows:—Victoria £11,189, New South Wales £11,136, South Australia £3,265, Tasmania £1,498, Western Australia £432; and the other half by the associated companies and the Indo-European Department of Her Majesty's Indian Government, the Extension Company's proportion being £17,770, the Eastern Company's proportion £7,862, the Indo-European Company's proportion £1,167, and the Indo Departments £721. As your Directors never expected that the entire loss would be recouped during the first year, they are not disappointed with this result, and have agreed to the experiment being continued for at least another year. In giving my own opinion upon this matter, it strikes me that the increase of traffic to which I have just referred is a very remarkable one indeed, and I have no hesitation in saying that we may look upon it in the future as permanent. At the same time, while I make that statement on this side of the table, we have to consult the Australian Colonies; but the payment which they have to make is so insignificant, compared with the

Digitized by Google

enormous advantages they are deriving, that I cannot for a moment suppose that they will hesitate to continue the reduced rates. The Company's repairing steamers have as usual been busily employed during the past half-year; but, owing to most of the cables being duplicated, the traffic has not been materially affected except with Manila, which, unfortunately, was cut off from telegraphic communication with the rest of the world for several weeks. The interruption was caused through the breaking of the cable between Hong Kong and Cape Bolinao at each end of the line during a severe typhoon. Negotiations are, however, proceeding with the Spanish Government for the duplication of the cable, and it is to be hoped that a satisfactory arrangement will soon be brought about. All the various sections of the Company's system are now in good working order. In accordance with the arrangement concluded with the Netherlands Government, and referred to in the last report, the Company's system has been extended during the half-year under review from Penang to Sumatra, the necessary cable having been taken from stock at Singapore, and the cost of the operation (£14,924) charged against the reserve fund. An arrangement has also been entered into for the manufacture and laying, on account of the Netherlands-Indian Government, of a cable to connect Acheen with the Company's new line at Sumatra; and the Telegraph Construction and Maintenance Company's s.s. "Seine" will this week leave the Thames with the requisite cable on board to carry out the work. A considerable business is carrried on between Sumatra and Penang, and it is therefore anticipated that the improved telegraphic facilities thus provided will in time prove important feeders to the Company's system. Now, gentlemen, the next matter I am going to draw your attention to is the staff pension fund. The shareholders having at the last meeting approved the principle of establishing a staff pension fund, your Directors have had a scheme prepared by experienced actuaries, who advise that an annual contribution by the Company of 2½ per cent. on the salaries, and a similar contribution by the staff, would, if invested at 4 per cent. compound interest, provide sufficient funds to make adequate retiring allowances for the younger members of the staff on their attaining 60 years of age, but as many of the older *employés* have already seen considerable service, and their retirement in some cases cannot be far distant, 2½ per cent. would be insufficient to place them on an equally favourable footing. With a view, therefore, to supplementing their allowances from the pension fund, the actuaries advise that, in addition to the 2½ per cent. just referred to, the Company should continue their present contribution to the endowment assurance fund in full until all the existing policies are paid off, and allow the savings effected by the premiums ceasing to be payable to the Assurance Company as the policies mature from time to time to be applied exclusively for the benefit of the older servants. The wish that the older servants should not be placed on a less favourable footing than the younger members of the staff was, I think, strongly expressed at the last meeting. The actuaries further recommend that the Company should guarantee 4 per cent. interest on the accumulations of the fund. Provision is also made in the actuarial calculations for dealing with cases of death or breaking down in health before reaching the retiring age, and for other contingencies. This is a fair outline of the actuaries' scheme; but as the various details are still under consideration by the Board, it is proposed to ask you to-day to approve a resolution in general terms empowering your Directors to bring the scheme into operation when the details are finally settled. Now, before leaving this subject, and before placing the resolution before you, I think it is right to tell you that no question has received more serious consideration than this, and I do not know that the shareholders can do better for the Company's interests than to carry out this scheme. It is important to secure an efficient staff, and it is important to see that their future is one of brightness, and not of darkness; and, on the whole, looking at the salaries they receive and the amount which they will receive from the pension fund, I think I may venture to say that very few of them would feel any inconvenience from being placed on the retired list, when they reach the retiring age. I am quite sure that the expense to the Company will be comparatively small. Years hence this question may be discussed again, and by intelligent people, probably in this room; and I desire, above all things, in bringing this matter now before you, that instead of being blamed hereafter for doing anything unjust either to one party or the other, the Board should be complimented upon the great care which they exercised, not only in the shareholders' interest, but also in the interest of the staff. This is a matter which cannot be finished in a day. We are giving every spare hour that we can to it. The actuaries are also giving it every attention, and every one in the concern, more or less interested, has had an opportunity of expressing an opinion on the subject. I, therefore, believe that we are going into this matter with thorough unanimity, and holding the opinion that it is for the Company's interests generally—the Directors bring it before you in the firm belief that it will meet with your hearty support. The resolution I have first to propose is as follows:—

"*That the report and accounts of the Directors now submitted be received and adopted; and that a dividend be now declared of 2s. 6d. per share, together with a bonus of 4s. per share, both free of income tax, payable on the 5th instant, making, with the previous distributions, a total payment of 7 per cent for the year 1891.*"

The Most Hon. the MARQUIS of TWEEDDALE: I beg to second the resolution.

Mr. JOHN NEWTON: I do not think that the resolution should be carried without an expression of opinion on the part of the shareholders in regard to the important step which you have taken relative to the staff.

The CHAIRMAN: I think that before that matter is discussed the resolution bearing upon it ought to be before the meeting.

Mr. NEWTON: I desire, then, to make a few remarks on another part of your speech. You have told us that since the amalgamation we have spent out of revenue and reserve in cable renewals and duplications £1,153,000; but in addition to that you have the reserve fund, which you stated amounted to nearly £500,000 more.

The CHAIRMAN: That is so.

Mr. NEWTON: That shows how much stronger the position of the Company is now than it was 20 years ago. All this amount has been added to our property, and at the same time we have paid a dividend averaging, I think, between 6 per cent. and 7 per cent. from the very commencement of the Company. That is a very satisfactory state of things, especially to those who were early shareholders, and I may state that I have been on the books of the Company for 18 years. Indirectly, I have also been connected with it through my interest in other companies. I desire to express my satisfaction at the position which the Company has now attained, inasmuch as we now feel that we have a property ranking with the highest class of securities in the Kingdom. I have before said that telegraph property now ranks with railway property. It can be as easily repaired; and it must be a gratification to everyone who has invested in telegraph property in the last 18 years to find that it has reached a point when it now yields to an investor only 4½ per cent. Of course, we have to take into consideration the reduction of interest generally upon joint-stock enterprise; but when we remember the enormous sums which have been lost in other undertakings in the same time, we have a great deal to be thankful for to the Directors for what they have done for us in so vastly strengthening the position of the Company.

The CHAIRMAN then put the resolution to the meeting in the usual way, and, having declared it carried unanimously, said the next resolution is:—

"*That John Denison Pender, Esq., who now retires by rotation, be and is hereby re-elected a Director of this Company.*"

Mr. FRANCIS A. BEVAN: I have great pleasure in seconding the resolution. Perhaps the Chairman could scarcely say anything about his own son, but I should like to inform the shareholders that I am sure they derive great benefit from having the son of the Chairman taking an active part in this Company. He is, I can assure you, a most efficient Director, and I have great pleasure in seconding the resolution for his re-election.

The motion was carried unanimously.

Mr. J. D. PENDER: I beg to thank you, gentlemen, for my re-election.

The CHAIRMAN: I have now to propose:—

"*That the Most Honourable the Marquis of Tweeddale, who now retires by rotation, be and is hereby re-elected a Director of this Company.*"

Mr. CHARLES W. EARLE: I beg to second the motion.

The resolution was carried unanimously.

The MARQUIS OF TWEEDDALE: I beg to thank you, gentlemen, for your renewed confidence.

Mr. FIELD: I beg to move:—

"*That Mr. Henry Dever and Messrs. Welton Jones and Co., be and are hereby re-elected auditors for the ensuing year at a remuneration of £100 each.*"

Mr. NEWTON: I second the resolution.

The motion was carried unanimously.

The CHAIRMAN: The next resolution which I have to propose is as follows:—

"*Resolved.—That this meeting approves of the establishment of a Staff Pension Fund and authorises the Directors to carry out the same upon such terms and conditions as they may think expedient.*"

I am asking you to give the Directors your full confidence in regard to this scheme. You have expressed yourselves warmly on previous occasions in regard to this subject; and I have been clear, I hope, and distinct in telling you that while we wish to benefit our staff, we shall be benefiting still more the interests of the Company. Even at a time like the present there is a demand for good telegraph clerks. We have trained not only good, but generally the best telegraph clerks in existence. We have an institution for the purpose, but we think it is very hard sometimes to find that after several years' training, these young men are encouraged to go elsewhere by higher salaries. We cannot object to that, for they have to make the best way they can in the world, but we think that if we make it their interest to stay with us we shall derive not only all the advantages of their early training and the expense we have incurred in that matter, but that we shall have people about us that we know something of; and it is our desire to make, if possible, the staff of this Company—who are now spread very much all over the world—feel that the best place for them is with the old Company. That is what we desire to do. The resolution will be seconded by Sir James Anderson, who knows all the details as well as any man living, and who takes a warm and deep interest in the staff; and you may rest assured that altogether the matter is in good hands.

Sir JAMES ANDERSON: I beg leave to second the resolution, and I have great pleasure in doing so.

Mr. JOHN NEWTON: I should now like to finish what I was going to say before. At the last meeting I suggested that the older members of the staff should be considered in this scheme, and I am glad that you have done so. In early years I was not altogether a *persona grata* with the Directors of this Company, and occasionally I had some contests with them on certain questions. At the same time I came into contact with several of the officials, and I was surprised at the great courtesy with which I was received by them, although I was in opposition to the Directors. When shareholders receive such treatment as this I think that they should express their opinion when a matter of this kind comes before them, that the older members of the staff should not be neglected. The younger members can look after themselves, because the future generation of our servants will be greatly benefited. The staff having an interest in this fund will see that it will be to their benefit that the Company should be prosperous, as if not there will be some peril to their pensions. You will

Digitized by Google

have an economical staff, and that will make up for what you may be sacrificing at the present moment. It is not, however, in my opinion a sacrifice that we are asked to make, but is really a further strengthening of the property, and making it a solid one for investors, because the property, scattered all over the world as it is, will be protected by a body of faithful servants, whose interest it is that the Company should prosper. As the junior members of the staff will be so greatly benefited in future years by what is now proposed to be done for them, I do think that the interests of the older members should not be overlooked, but that they should have the full benefit of any allowance we may make if they should have to retire next year. The property is so greatly improved that you need not fear that you will have the hearty approval of the shareholders of the Company in giving a proper measure of justice to the old servants of the Company.

The CHAIRMAN then put the resolution, which was carried unanimously. Continuing, he said: I think that I have pretty well exhausted all the subjects which had to be brought before you on this occasion. I have put down a few notes here, but I think that what I have said and read will convince you that a very satisfactory state of things exists in connection with our Company. I can only say that, good as our position is to-day, I see no reason why it should not continue so in the future.

Mr. BLUNDELL: Before the meeting separates I have much pleasure in proposing a resolution, which I am quite sure will be carried *nem. con.*, like the others—that is, that the best thanks of the meeting be given to the Directors for their services during the past half-year, and to the Chairman for his conduct in the chair to-day. I can only congratulate them upon having brought their labours to so satisfactory a conclusion, and I trust that they may be long spared to rule over the Company in the same efficient manner as they have done in the past.

Mr. W. GRIFFITH: I have very much pleasure in seconding the resolution.

The motion was carried unanimously.

The CHAIRMAN: On behalf of my colleagues and myself I have the greatest possible pleasure in thanking you. I may tell you that I have come here to-day with the strongest possible desire not to break my record. I have attended every public meeting of this Company since its inception. For the last fourteen days I have been confined to my room by bronchitis. I have not escaped the penalties which men in all stages of life have been subject to, but I thought it was my duty to make an effort to come among you to day. This is my first day out, and I only hope that it is the beginning of my complete restoration to health.

The proceedings then terminated.

Brazilian Submarine Telegraph Company (Limited).

The thirty-seventh ordinary general meeting of the shareholders of this Company was held at Winchester House, Old Broad-street, on Wednesday, under the presidency of Sir James Anderson.

The SECRETARY (Mr. Richard Collett) read the notice calling the meeting, and the minutes of the previous general meeting, which were confirmed by the present meeting and signed by the Chairman as correct. The report of the Directors was taken as read.

The CHAIRMAN then said: Gentlemen, as you have had the report and accounts before you for some time, I presume I need not do more than, as usual, call your attention to some of the salient points. There is a decrease of revenue of £31,819 as compared with the previous half-year; but I must remind you that the accounts of several of the previous half-years have included abnormally large receipts arising from exceptional causes in South America, with which you are well acquainted. The existence of a more settled state of affairs has resulted in a falling-off of the exceptional traffic, and this accounts partly for the above large decrease. It is, however, chiefly due to the abnormally low rates of exchange which existed in Brazil during the half-year under review, and which, I am sorry to say, still continue. We can only hope that by-and-by the value of the Brazilian currency will improve. There has been an increase on the expenditure side of £7,037; of this, £3,422 is an increase in cost of repairs of cables, which, last half-year, was £13,450, as compared with £10,028 in the half-year before that. We must, of course, be at all times prepared for expenditure upon repairs. Then there has been part of the cost of duplexing our newest cable, amounting to £3,000, and £587, the cost of training the necessary operators to work duplex, and further strengthen our staff for a continuous day and night service, so as to create a speed and accuracy which cannot be excelled, and I hope will not be easily equalled when our joint system is duplicated and duplexed, and certainly not with single cables, which is all our rivals have yet projected. After paying two interim quarterly dividends at the rate of 6 per cent. per annum, we carry forward the sum of £19,893, and I shall be disappointed if you do not as usual receive a bonus at the end of the financial year payable in October. I am glad to say the current half-year's working is not unsatisfactory. There is one other matter I should like to refer to. You are aware that the cables of the Western and Brazilian Company are partly duplicated, and that it required the laying of a second cable between Santos and Chuy, to provide a complete duplicate system between Great Britain and Buenos Ayres. The want of this complete duplication prevented the service with the River Plate being entirely satisfactory to your Directors as a strong competing line, and as it is at Buenos Ayres that the Central and South American Company can best compete for traffic, we have arranged with the Western and Brazilian Company that they shall lay the necessary cable. The cable is now being laid, and will, I believe, be landed to-day, and I am sure this cable will lead to results greatly to our mutual advantage and success in dealing with our competitors. The cost incurred by the Western Company has been very large, and as the Brazilian Company's fair contribution your Directors have agreed to pay that Company a fixed sum of £6,000 per annum instead of making any alteration in the percentages of the joint purse. In addition to the advantage of the extra cable the Western Company give us the right to use their repairing ship for repairs of our cables off the coast of Brazil at a moderate charge per day. In certain cases this arrangement will save the expense of fitting out a steamer in Europe, with the long journey to Brazil and back. I think I need not further dilate upon the revenue or expenditure, but go on to what I have to say in regard to the present and future aspect of our affairs, as this subject presses more upon my own mind, as I dare say it does upon yours. First, then, it is true our existing rival on the West Coast of America has forestalled us in securing the trans-Andine line between Buenos Ayres and Valparaiso, and has so arranged his tariffs as to shut us out for the present from any share in the Chilian and Peruvian traffic, but the companies interested in passing this traffic by the East Coast route, namely, the West Coast of America Company, the Western Brazilian, and this Company, are arranging for the construction of an independent trans-Andine line of improved character between the Atlantic and the Pacific, and we shall then see how far our rival—the Central and South American Company—can retain the ground it has taken. The Central American Company has commenced cutting rates. We had carried out a policy of gradual reduction as circumstances permitted, ranging from 33 to 50 per cent. of the old rates, according to locality, and we should no doubt have continued this policy had not these rival cable projects sprung up. We have not initiated a war of tariffs, nor have we yet gone so far in reductions as our West Coast rival, but we are prepared, whenever we see it to be in your interests, to accept the challenge. We shall certainly not remain at a higher tariff than our rivals when the time comes to accept the position, and in the meantime we are daily watching the course of traffic and safeguarding your money and interests with care and forethought. I may now refer to our second rival, the Antilles Cable. This company has not made any mark so far, and it is certainly not to their interest to reduce tariffs. I think they must be watching with some anxiety the development of the other rival lines. Of course we know what the French Antilles Company are trying to do, but unless they have Government subsidies it does not appear to us that they are in an enviable position. For all that, they must not be despised; they have spent a great deal of money, must expend a great deal more, and we may have to count with their opposition by-and-by. And now we have a third rival in the new Company—the South American Cable Company—just put before the public. That company proposes to unite Africa with Brazil by a cable between Senegal and Pernambuco, and so provide another route to Europe *via* Africa. I may remind you that Africa is already joined to Brazil, and the route to Europe is already in existence, as your cables at St. Vincent are in connection with that of the African Direct Telegraph Company, and in fact with the whole world. I am personally sorry we must oppose them, as we are individually on friendly terms, but the attack is from them, not from us. I do not think I should have felt it my duty to say anything against the company, whatever I might have thought, because contractors have a right to keep their machinery going if the public will find the money, or if they are rich enough to risk their own money. But the body and bones of the prospectus is that they hold this Company up as the one they intend to injure, and they base their estimates of revenue on a few exceptional years, when civil war by sea and land, revolution and financial crisis, caused reckless telegraphing and expenditure, which naturally inflated our receipts at a time when every other means of communication with the outer world than by our East Coast cables was stopped; and the prospectus complacently assumes that the new Company may reasonably expect to take from this Company £85,000 per annum of such extraordinary receipts, which have, however, since the advent of peace, already diminished, from one cause or another, by one-third. The tariffs are reduced, and certain to be still more reduced, while the loss on exchange on the charges collected in Brazil is equivalent to another very large reduction. Their prospectus says, in short, "This Brazilian Company has made a lot of money—will the public join us in a speculation to take as much as possible from them?" and they give data which I can assure them will prove disappointing. Well, the company is formed, the cable has been manufactured, the ship has sailed with it, and we shall just have to meet its opposition. On the last occasion of my addressing you it was said that I had made a pessimistic speech, and I dare say I did. One cannot see three rival companies attacking, or preparing to attack, our traffic, and speak to the proprietors as if it were an amusing trifle. At the same time, I was not, and said I was not, in any mood to despond, and neither I nor my colleagues are now in any fearful state of mind. Of course we are anxious, but so far as lies in our power, we will prevent our rivals taking from us that £85,000, or anything like it. We can look with great satisfaction upon our position. The entire system of the Brazilian Company is duplicated, and the newer cable is duplexed, giving practically the carrying capacity of three cables; the duplication of the cables of our partners, the Western and Brazilian Company, between our point of landing at Pernambuco and the River Plate, will be completed to-day or to-morrow, and the duplex working between London and the River Plate will then be arranged for. So far none of our rivals have projected more than a single cable each. Our traffic is being transmitted with great speed, which we are improving every month. We have duplicated our cables without increasing our capital, and we have a substantial reserve in available sovereigns for extensions or contingencies. We do not derive our revenue from South American traffic only, our receipts from the West Coast of Africa and the Cape Colonies being of considerable importance, but of this our rivals did not take any note, making their calculation as if all our revenue resulted from the traffic carried between Pernambuco and Europe; and, as I have already said, we shall soon have a direct line across the Andes to Chili, and all the way to Lima; in fact, a complete through communication from Peru and Chili to Great Britain and Europe. Gentlemen, we cannot make your position better; nothing that forethought or a judicious expenditure of your money could have done to strengthen

Digitized by Google

the position of your Company has, in my opinion, been neglected, and with a continuance of this policy, we may look the future in the face with as much equanimity as the proprietors of any enterprise in the world of such a public nature can regard their present or future prospects. That is all I need say. I do not at all fear the result of this competition, come when it may. Having our lines duplicated and duplexed, we are in as strong a position as we can be, and we must wait and see the result. I have now to propose the following resolution :—

"That the report of the Directors, and the accounts to December 31, 1891, now submitted, be approved and adopted."

The Hon. W. ST. JOHN F. BRODRICK, M.P., seconded the motion.

A brief discussion followed, and, in answer to questions,

The CHAIRMAN said that the cost of the Transandine Line would be about £100,000—perhaps, £120,000, and it would be done by debentures, he thought, with a little capital, if necessary. This Company's share of the cost would be one-half, but he did not expect any loss on it, as the traffic on it would pay very well. They had gone very carefully into the matter. The new South American cable was expected by those interested in it to be open for traffic in July next. A project was being discussed in Lisbon as to giving the Company an extension of their monopoly for 10 years, and the Eastern Company a similar advantage, if they would connect Lisbon with the Azores. The French Company were, however, trying very hard to get the work, and therefore he did not know whether the Brazilian Submarine Company would get it. If they did, it would be a splendid monopoly for another 10 years, but it would cost them £50,000. The matter, however, was now under discussion. He then put the resolution, which was unanimously adopted.

Mr. ROUGHTON then proposed a vote of thanks to the Chairman and Directors.

Dr. H. ELLERY TREWHELLA seconded the motion, observing that the shareholders must have seen that they had a Board who were most vigilant in looking after their interests. As regarded their Chairman, he had never listened to more cautious remarks than those which had been made by Sir James Anderson on that occasion.

The CHAIRMAN, in acknowledging the vote, assured them that the past six months had been about as anxious a period as they had ever had. He was much obliged to them for the confidence which they had shown in the Directors.

The meeting then separated.

Submarine Cables Trust.

The twenty-first ordinary annual meeting of the certificate holders of the Submarine Cables Trust was held yesterday at the offices, Winchester House, Old Broad-street ; Sir John Pender, K.C.M.G., in the chair.

Mr. CAMBROOK (for the Secretary) read the notice calling the meeting and the minutes of the last meeting, which were approved by the present meeting, and signed by the Chairman.

The CHAIRMAN : Gentlemen, I will now give you a short statement of the position of the Company and of its revenue during the past year. The revenue for the past year amounted to £22,799, as against £23,666 in 1891, showing a decrease of £867. In the previous year the trustees made a small profit of £264 on a temporary investment of their current balances, and the income derived from our investment in Anglo-American stock is about £600 less than in 1891. The expenses for the year amounted to £1,186, as compared with £1,175, or a small increase of £11. The trustees beg to remind the certificate holders that the cost of administering the Trust is £813 under the amount provided by the trust deed. This is due in a great measure to the trustees not having filled up the vacancies as they occurred by the death of two of their colleagues. The trustees, however, think the time has now come when these vacancies should be filled, and they have considered it judicious to select two younger men, who nevertheless have considerable experience in submarine telegraph business, and knowledge of the securities in which the capital of the Trust is invested. The names of the two gentlemen are Mr. John Denison Pender and Mr. Kenneth Anderson, and a resolution will be put before you on the subject. We have paid during the year £7. 2s. 6d., but the balance brought forward from last year was equivalent to 15s. 7d. per cent. on the value of the outstanding certificates. Our revenue during the past year has been sufficient to meet two coupons of £3 each, and pay off about an additional 7s. of the overdue coupon. There remains still a balance of £1. 17s. 6d. in arrear, but should the dividend on our holding in Anglo-American Stock improve, and the income from our other investments be maintained, we trust this arrear will be gradually paid off. We hope to pay the balance of the coupon due April 15th on or about August 1st next. I think it right to state that a Trust of this kind requires the people concerned in its management to be more or less constantly in attendance, and therefore our proposed introduction of new blood into it is the right course to take. Some of us are getting into life, and our attendance may not be so regular as we could wish, but there must be always men in attendance to look after the work of the Trust. The suggestion which has been made to you as to the election of new trustees to supply the vacancies in that body was decided upon after considerable thought, and with the knowledge that the young men suggested for the positions know exactly the nature of the Trust, and they will also be in touch with the general public as to the value of the stocks we hold. For instance, Mr. Kenneth Anderson knows something of what is going on outside, while Mr. John Denison Pender knows perfectly well all that is going on inside. They know the nature of the Trust and of the investments, and I do not think we could have suggested two better men to fill the position of trustees. I now propose—

"That the report and accounts of the trustees to April 15, 1892, submitted to this meeting, be and the same are hereby received and adopted."

Sir JAMES ANDERSON : I second the resolution.

The motion was carried unanimously.

The CHAIRMAN : I will now propose the second resolution, which, I may state, has been specially prepared by our solicitors. It is as follows. Resolved—

"That John Denison Pender, of 51, Sloane-street, in the County of Middlesex, Esquire, and Kenneth Anderson, of 19, Ashburn-place, South Kensington, in the County of Middlesex, Esquire, be and are hereby appointed Trustees of the Indenture dated September 6, 1871, and made between Sir James Anderson, Sir Daniel Gooch, Bart., Lord William Hay, Viscount Monck, Captain Sherard Osborn, R.N., and John Pender, Esq., of the one part, and Philip Rose, Esq. (for and on behalf of all the holders for the time being of certificates thereinafter mentioned), of the other part, in the place of Sir Daniel Gooch, Bart., and Captain Sherard Osborn, R.N., respectively deceased."

The Most Hon. the MARQUIS OF TWEEDDALE : I will second that.

The resolution was carried unanimously.

Mr. E. CUNLIFFE OWEN then proposed the following resolution :—

"That Mr. John G. Griffiths and Mr. John Gane, both of whom now retire, be, and they are hereby re-elected auditors of the Trust for the current year, at a remuneration of £25 each."

Mr. BURMAN seconded the motion, which was carried unanimously.

The CHAIRMAN : I may mention that this Trust is of a peculiar nature. It is practically a tontine, which will wind itself up in a certain number of years, and therefore we require youthful men to see the end of it. Probably the young men you have appointed to-day will have to elect others hereafter to succeed them, but at all events it is a self winding up institution.

Mr. BURMAN then proposed a vote of thanks to the Chairman and Directors.

Mr. WILLIAM SHUTER seconded the motion, which was carried unanimously.

The CHAIRMAN : On behalf of my co-trustees and myself I am very much obliged to you. Trust Companies have been very much before the world for the last two or three years, but I think that ours will bear very close inspection indeed, and I feel sure that the more they are looked into the more they will be appreciated.

The proceedings then terminated.

Great Northern Telegraph Company.

The following is an abridged report of the proceedings at the general meeting held at Copenhagen, on the 30th ult. ; Mr. F. Zahle presiding.

The Chairman of the Company. Mr. C. F. TIETGEN, in rendering an account of the working of the Company during the year 1891, referred to the Company's cables, which, he said, had, on the whole, been working normally. In Europe the interruptions had actually been less frequent than in 1890, although the number of cables was at the present moment 12, or 16 if counted by sections, and the Company's cable steamer, "H. C. Örsted," had remained in port during nine months of the year. In the Far East the number of cables was now 9, or 13 if counted by sections, the system having been reduced by the sale to the Japanese Government of two small sections of the cable between Korea and Japan. The interruptions had been nearly as frequent as in 1890, the cable steamer "Store Nordiske" having been on active service for 187 days, of which, however, 66 days had been for account of others.

New Cable.—Although the new concession granted by the French Government was not ratified until June last, the laying of the duplicate cable between France and Denmark had been successfully carried out during the latter half of July. This cable, which had been manufactured by the Telegraph Construction and Maintenance Company (Limited), of London, was about 370 nautical miles long, and the core and armature had been chosen with the special view of securing an electrically and mechanically perfect cable of the most solid description. The effect of the establishment of this duplicate line had already shown itself in the greater amount of traffic and in the increased regularity and speed of transmission. The landplaces on the French and Danish coasts were the same as those of the old cable, but the new cable was laid in a track as far removed from the old one as practicable, in order to prevent simultaneous interruptions of both cables from the same cause.

New Premises in Copenhagen.—Although it would take a year or two before the Company's new premises in Copenhagen would be completed, the general offices, as well as the workshops of the Company, had already been established there since last autumn. The accommodation in the new house had given entire satisfaction in every respect, and the considerable extension of the workshops had rendered it possible to execute outside orders with greater promptitude than hitherto. Such orders had not been wanting during the past year, in fact they had contributed greatly towards reducing the amount charged to the working account under the item of "Instruments and Cells."

The Situation in China and Japan.—The anti-foreign riots, which had agitated the Chinese Empire during part of the year, had not interfered with the Company's business in any way. In one of the interior provinces, however, the animosity of the rioters against the telegraph had vented itself in the destruction of thousands of telegraph poles belonging to the Chinese Administration, and intended for the construction of an internal line. This occurrence was an additional proof of how indispensable submarine cables were in China, and how little foresight was displayed by those who agitated in favour of landlines to the detriment of the submarine connections. In Japan, the calamity brought about by the terrible earthquakes had awakened the sympathy of all, and the Board of Directors

Digitized by Google

felt sure that, in assisting the relief committee in various ways, besides subscribing, on behalf of the Company, $2,000 for the benefit of the sufferers, they had only been acting in accordance with the wishes of the shareholders. The same remarks applied to a subscription of Rbls.5,000 to the fund raised for the relief of the distress in Russia; in both countries the Company had enjoyed protection and hospitality for a quarter of a century.

Traffic Receipts.—These had been most satisfactory during the first six months, in which they had even exceeded those of the corresponding period of the previous year. On 1st July, however, the tariff reductions fixed by the International Telegraph Conference at Paris, came into force, and these had caused a marked falling-off in the receipts for the rest of the year. When it was further taken into consideration that the embargo on the export of grain from Russia had very much affected the traffic, and that the rate of exchange on the remittances from the Far East had steadily declined, it would be easily understood that the advantage gained during the first half of the year had, to a great extent, been lost during the latter half. The effect of the depreciation in the value of silver currency had, in fact, been so great, that the "tael" which in August, 1890, was worth about 5s. 3d., was, at the present moment worth only about 3s. 10d., representing a loss of over 25 per cent. on all the receipts collected at the Company's stations in the Far East. Notwithstanding this, the total gross receipts were a little higher, while the expenses, thanks to the profits realised by the Company's workshops and cable steamers, were somewhat lower than in 1890.

Distribution of Profits, &c.—In the above circumstances the Board of Directors consider themselves justified in recommending that the total dividend be fixed at the same figure as last year, say, 17s. 2d. per £10 share, or about 8·60 per cent. In accordance with the intentions expressed in the last report, the Company had laid the very costly new cables without having drawn upon the investments of the reserve fund. On the other hand, however, the cash placed to the credit of that fund, and the amounts carried forward during the last two years, had been completely absorbed by those heavy expenses. In order to gradually counterbalance this, it had, therefore, become necessary to somewhat increase the usual addition to the reserve fund, and the amount carried forward to the following year.

Representatives abroad.—W. de Hedemann, Esq., who had represented the Company in St. Petersburg since 1876, had been forced to retire, owing to failing health, and had been replaced by F. Kiær, Esq.

The proposals that—

(1) "*The report and balance-sheet, together with the propositions as to the distribution of the balance, be adopted and discharge given to the Board of Directors;*"

(2) "*That the retiring Director, Colonel V. Hoskier, be re-elected as member of the Board of Directors;*"

(3) "*That A. Berner, Esq., and S. Bille, Esq., be re-elected as auditors of the Company*"

were submitted to the meeting, and carried unanimously.

Elmore's American and Canadian Patent Copper Depositing Company (Limited).

The first general meeting of this Company was held on Tuesday, at the Cannon-street Hotel, Sir Francis de Winton presiding.

The SECRETARY (Mr. J. Shurmer) having read the notice calling the meeting,

The CHAIRMAN stated that it was simply the statutory meeting which was required to be held within four months after the registration of the Company, and there was, therefore, little or no business to be transacted. They proposed, however, to ask them to sanction an alteration in the Articles of Association in order to comply with the requirements of the Stock Exchange Committee, of whom they had asked for a special settlement and official quotation of their shares. The Committee, however, first of all required them to rescind Clause 92 of the Articles of Association, which was as follows;—

> "92. The Directors shall have full power to execute, in the name and on behalf of the Company, in favour of any Director or other person who may incur or be about to incur any personal liability, whether as principal or surety, for the benefit of the Company, such mortgages or charges of the Company's property (present and future) or uncalled capital as they think fit by way of guarantee to or for the indemnity of such Director or person, and any such mortgage or charge may contain a power of sale and such other powers, covenants, and provisions as shall be agreed on."

The elimination of this clause was entirely in accordance with the shareholders' interest. Out of the 65,000 priority shares offered to the public for subscription, 45,000 had been allotted among 700 applicants, and comparatively a small amount only was outstanding on calls. No time had been lost in obtaining tenders for supplying the plant required to be erected in America to carry out the objects of the Company; and they further hoped, by arrangement with the Directors of the other Elmore companies, to invite the experts of intending purchasers to visit the works of the English and French companies, and thus to show them the real success of the process on a large commercial scale. Difficulties had always to be encountered in putting up new works and starting a new process, but if allowance were made for these drawbacks it would be found that little time had been wasted since the formation of the first Elmore company, and he had no reason to doubt that the English companies were now in a satisfactory condition. If that were the case in one country, it followed that the same could be done in other countries (with proper management) where there was a considerable copper consumption; and he was convinced that in the American and Canadian Company the shareholders had an investment inferior to none of the others. It must be borne in mind that their Company was not formed for the purpose of manufacture, but to exhibit and resell the American and Canadian patents. It was, therefore, most unlikely that there would be any delay in their operations, such as had had to be encountered by the European manufacturing companies. The fully paid share certificates of the Company were ready to be issued in exchange for allotment letters and bankers' receipts. He then proposed the following resolution:—

"*That Clause 92 of the Company's Articles of Association be and is hereby rescinded and annulled.*"

Colonel P. MOSELY seconded the motion.

The CHAIMAN, in answer to a question, stated that, as set out in the prospectus, the Company was formed simply to resell their patents. They proposed to put up a small plant in America in order to demonstrate the practicability and the commercial value of the process; but with the large companies in England and France already working, it would be spending the shareholders' money in a doubtful way to work the process in America.

The resolution was carried, and a vote of thanks to the Chairman brought the meeting to a close.

Western and Brazilian Telegraph Company (Limited).

The following is the report of the Directors to be presented at the twenty-third ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., on Thursday next, May 12th, at 12 noon:—

The total earnings for the half-year ended 31st December, 1891, amount to £92,345. 4s. 7d., as against £108,817. 10s. 5d., showing a decrease of £16,472. 5s. 10d. compared with the half-year to 31st December, 1890. It will be observed that in common with other South American undertakings the loss on exchange is heavy, and in this Company's case reaches the large sum of £19,133. 16s. 5d. But for this loss the revenue would have been in excess of that for the corresponding period. The working expenses amount to £38,404. 5s. 1d., as against £37,200. 2s. 4d., an increase of £1,204. 2s. 9d.

Including the amount brought forward from 30th June, 1891 (£6,470. 4s. 8d.) and the dividend received upon the shares held in the "Platino" Company, the balance to the credit of the revenue account is £67,798. 4s. 2d. from which has been deducted £12,807 for debenture interest, and £6,293 for the debenture redemption fund, leaving £48,698. 4s. 2d., of which £15,000 has been placed to the reserve fund. The Directors now recommend the payment of a dividend of 6s. per share, free of income-tax, for the half-year on the ordinary shares, making with the dividend paid in November last, £4 per cent. for the year, leaving a balance of £4,486. 18s. 2d. to be carried forward. In the case of shares which have been divided into "Preferred" and "Deferred," 1s. 6d. per share of the dividend now recommended will be payable to the "Preferred" shareholders, and 4s. 6d. per share to the "Deferred" shareholders.

The third annual drawing of the A and B debentures took place at the Company's offices on January 15th last, when debentures amounting to £12,700 were drawn, and have since been paid off at par.

Under a satisfactory arrangement with the Brazilian Submarine Telegraph Company a contact for the immediate duplication for the Company's lines between Santos and Chuy has been entered into with the Telegraph Construction and Maintenance Company (Limited), and the expedition to lay the cable is now on its way out. Upon the completion of this additional line, and in consideration thereof, this Company will receive a payment of £6,000 per annum from the Brazilian Submarine Telegraph Company. When this cable is laid the lines of the Company will be duplicated over the whole of the busy part of the system, namely from Pernambuco to Monte Video; thus affording, in connection with the through lines working in concert with this Company, duplicate lines from Europe to Brazil, Uruguay and the Argentine Republic. The new cable will be duplexed throughout.

The Company has entered into a contract for a new repairing steamer in substitution of the "Norseman." The new ship will be of the best and most recent construction; will be more economically worked, possess greater speed and be more handy in the moderate depths with which the Company will now have to deal. As soon as she reaches her station, efforts will be made to dispose of the "Norseman."

The dividend warrants will be posted on the 13th May, 1892.

The retiring Directors are Mr. C. W. Earle and Mr. D. H. Goodsall, who offer themselves for re election. Notice has been given to the Company that Mr. John Coppen is willing to serve as a Director, and that at the general meeting on the 12th May he will be proposed for election. The shareholders are aware that at the last general meeting the Directors stated that it was not their intention to add to their number, as they did not see their way to fill adequately the place at the Board vacated by Mr. Weave. The Directors are of opinion that the appointment of an additional Director would be of no advantage in the management of the Company's affairs, unless he possessed knowledge and experience of the business of a telegraph and cable company, or special knowledge and influence calculated to be useful to the Company in South America. There is a sufficiency already of general business qualifications at the Board. Under these circumstances, the Directors see no reason to depart from the conclusion announced to the proprietary last November, and coincided in by a fully attended meeting of the shareholders.

The auditors suggest that in future their respective firms should be elected in lieu of themselves as individual partners, and the resolution for the election of auditors should accordingly take this form, viz.:—"That Messrs. Turquand, Youngs, Weise, Bishop and Clarke, and Messrs. Deloitte, Dever, Griffiths and Co., be elected auditors of the Company, and that their joint remuneration (as heretofore) be one hundred guineas."

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

ENGINEERING EXCHANGE (LIMITED).—This Company was registered on April 26, 1892, with a capital of £10,000, in £10 shares, to provide, regulate and maintain a suitable building, room or rooms, for an Engineering Exchange or Exchanges in the County of London; to acquire, preserve and disseminate useful information connected with the engineering interest, throughout all markets, and generally to promote engineering business. The signatories are:—Reginald Bolton (5 shares), Arthur T. Salisbury-Jones (5), Wyndham Payne-Gallwey, hydraulic engineer (1), J. J. Dale (1), Fred. B. Nicholson, electrical engineer (1), Charles W. Potter (1), W. J. P. Moore (1).

PAYNE-GALLWEY, PICKERING AND CO. (LIMITED).—This Company was registered on April 26, 1892, with a capital of £20,000 in £1 shares, by Jordan and Sons, 120, Chancery-lane, W.C. The objects are to carry on the business of gas, pneumatic, steam, hydraulic and electrical engineers, machinists, iron, brass, and other metal founders, iron, tin, copper, zinc, lead and other plate workers, copper smelters, &c.

SHEFFIELD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This Company was registered on May 3, 1892, with a capital of £98,000, divided into 14,000 shares of £7 each, by Charles Doubble, 14, Serjeants'-inn, Temple, E.C. The objects are to acquire and take over as a going concern the electric lighting and electrical fitting business of the Sheffield Telephone Exchange and Electric Light Company (Limited), together with the assets and liabilities of that Company, and with a view thereto to enter into and carry into effect the agreement referred to in Clause 2 of the Articles. To carry on at Sheffield and elsewhere the business of an electric light company in all its branches, to generate, accumulate, distribute and supply electricity, and to do all things incident thereto. To carry on the business of electricians, mechanical engineers, ironfounders, brassfounders, metal workers, metallurgists, chemists, wire insulators, glass and indiarubber manufacturers, and, if thought fit, the business of a telephone company. The signatories to the Memorandum and Articles of Association are:—John Tasker, Joseph Gamble, George Senior, George Franklin, William Tasker, Frederick Tasker, John H. R. Tasker. The Directors shall forthwith enter into an agreement with the Sheffield Telephone Exchange and Electric Light Company (Limited) in the terms of the draft, a copy whereof has for the purpose of identification been subscribed, and the Directors shall carry the said agreement into effect.

WESTERN COUNTIES ELECTRIC LIGHT AND POWER SYNDICATE (LIMITED).—This Company was registered on April 26, 1892, with a capital of £25,000, divided into 380 ordinary and 120 deferred shares, of £50 each, by Jordan and Sons, 120, Chancery-lane, W.C. The objects are to adopt and carry into effect an agreement, dated April 22, 1892, between George J. Parfitt and George J. T. J. Parfitt, of the one part, and Samuel F. Andrews (as trustee for and on behalf of this Company), of the other part, for the acquisition of the business of electrical engineers now carried on by Messrs. George Parfitt and Son, at Keynsham, in the County of Somerset, with all the patent rights, privileges, concessions, contracts, wayleaves, installations, workshops, machinery, plant, &c. To carry on and continue the said business, and generally to carry on the business of an electric light and power company in all its branches. To carry on the business of electrical and mechanical engineers, and manufacturers of and dealers in electric, magnetic, telegraphic, telephonic, and other appliances and apparatus. The signatories are J. H. Clifton, Henry R. Wansbrough, H. A. Hood Daniel, Jno. C. Gilmore, J. Bligh Bond, G. Wilton and Charles Harrison.

MISCELLANEOUS.—BOOTS (LIMITED), wholesale chemists and druggists and dealers in electrical and scientific apparatus; capital, £100,000, in £1 shares.—JOHN WHITELEY AND SONS (LIMITED), wire manufacturers, mechanical and electrical engineers, &c.; capital, £100,000, in £5 shares.—SMOKELESS BOILER AND ENGINEERING COMPANY (LIMITED), boiler and furnace makers, mechanical and electrical engineers, &c.; capital, £100,000, in £5 shares.—T. POTTER AND SONS (LIMITED), general engineers; capital, £20,000, in £1 shares.—WAVERLEY (LIMITED), typewriter manufacturers, mechanical and electrical engineers, &c.; capital, £75,000, in £1 shares.

BIRMINGHAM ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of the above-named Company, made up to March 3, 1892, was filed on April 26th. The Company was registered on December 2, 1889, with a capital of £100,000, in £5 shares. At the time of making up, 17,173 of the 20,000 shares had been taken up, and upon 1,006 of these the full amount had been called, while upon the remaining 7,167 shares, £1 per share had been called. The calls paid amount to £57,174. 10s., leaving £22. 10s. as yet unpaid.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—The annual return of the above-named Company, made up to October 5, 1891, was filed on March 8, 1892. The Company was registered on August 10, 1889, with a capital of £750,000, divided into 150,000 preference shares, of £2 each, and 150,000 ordinary shares, of £3 each. At the time of making-up 77,978 ordinary and 69,996 preference shares had been taken up. Upon all these shares the full amounts had been called, resulting in the payment of £373,923. 10s., and leaving £2. 10s. as yet in arrears.

DALZIEL'S NEWS AGENCY OF AMERICA (LIMITED).—The statutory return of the above-named Company, made up to April 11, 1892, was filed on April 13th following. The Company was registered on November 14, 1891, with a capital of £100,000, divided into 5,000 "A" and 5,000 "B" shares of £10 each. At the time of making up, 1,500 'A" and 2,500 "B" shares had been taken up, of which 500 "A" and 2,500 "B" shares had been issued as fully paid to Dalziel's Cable News Agency (Limited). Upon the remaining 1,000 "A" shares, £7 per share has been called, resulting in the payment (including £1,302 paid in advance of calls) of £8,148, and leaving £154 unpaid (including £10 due on allotment).

DAVIS AND TIMMINS (LIMITED).—The annual return of the above-named Company, made up to October 20, 1891, was filed on March 11, 1892. The Company was registered on July 25, 1884, with a capital of £10,000, in £10 shares. By special resolutions in 1887 the capital was raised to £20,000 by the creation of 1,000 new shares of £10 each. At the time of making up, 1,253 shares had been taken up, of which 200 fully-paid shares had been allotted to Mr. Emile Davis, and 100 fully-paid up shares had been allotted to Heyne Brothers, of Offenbach, Germany, pursuant to agreements filed. Upon the remaining shares the full amounts have been called, and all calls (£9,530) have been paid.

ELECTRICITY SUPPLY CORPORATION (LIMITED).—At extraordinary general meetings of the members of this Company, on March 29 and April 13, 1892, the following special resolutions were passed and confirmed:—(1) "That the capital be reduced by cancelling the 100 founders' shares of £10 each, which have not been taken or agreed to be taken by any person." (2) "That each of the remaining £10 shares be divided into two £5 shares, upon each of which the amount to be credited as paid up shall bear the same proportion to the sum of £5 that the amount now credited as paid up upon the whole share bears to the sum of £10." (3) "That the capital of the Company be increased to £150,000 by the creation of 200 new shares of £5 each."

GRANGE SYNDICATE (LIMITED).—A notice was filed on April 2, 1892, that Mr. Justice Stirling, on Saturday, March 19, 1892, ordered that this syndicate be wound up, and that Mr. Charles John Stewart, the official receiver attached to this Court, was constituted provisional liquidator. The above-named Company was registered on August 1, 1890, with a capital of £2,000, in £5 shares, to assist in the development and demonstrations of the utility of Groth's electric tanning system. The last annual return, made up to January 13, 1892, and filed on January 21st following, shows that 330 of the 400 £5 shares had been taken up, the full amount called, and £1,550 out of £1,650 paid.

HASTINGS AND ST. LEONARD'S-ON-SEA ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 9, 1892, was filed on February 15th following. The Company was registered on March 7, 1882, with a capital of £50,000, in £10 shares; and, at the time of making-up, 843 shares had been taken up, and the full amount called. The total amount received, including payments on application and allotment, is £8,385, and the calls unpaid amount to £45.

HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY (LIMITED).—The annual return of the above-named Company, made up to April 19, 1892, was filed on the 29th. The Company was registered on February 20, 1888, with a capital of £350,000, divided into 57,900 ordinary, 12,000 preference, and 100 founders' shares of £5 each. At the time of making-up, 8,322 ordinary, 2,800 preference, and 100 founders' shares had been taken up, of which the founders' and 1,000 ordinary shares had been issued as fully paid. Upon the remaining 7,322 ordinary and the 2,800 preference shares, the full amount had been called, resulting in the payment of £50,210, and leaving £400 in arrears.

NOTTING HILL ELECTRIC LIGHTING COMPANY (LIMITED.)—The annual return of the above-named Company, made up to April 14, 1892, was filed on April 28th following. The Company was registered on February 21, 1888, with a capital of £100,000, divided into 9,450 ordinary shares of £10 each, and 550 founders' of £10 each. At the time of making-up, 6,452 ordinary and 550 founders' shares had been taken up. Upon all of these the full amount has been called, and as a result all the calls (70,020) have been paid.

CITY NOTES, &c.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—Notice has been given this week of the first drawing of 5½9 Four per Cent. Debentures, which took place yesterday (Thursday) at the offices of the Company.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended May 1st were £794, as against £733 for the corresponding period of last year, being an increase of £61. The total receipts to date, from January 1st last, amount to £14,418, against £13,247 in the corresponding period of 1891, being an increase of £1,171.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of April were £3,700, as compared with £3,760 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the month of April amounted to £1,785, as compared with £1,825 in the corresponding period of last year, a decrease of £40.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of April amounted to £53,683, as against £60,909 in the corresponding period of last year, a decrease of £7,226.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of April amounted to £38,824, and to £44,729 in the corresponding period of last year, a decrease of £5,905.

ELMORE'S AMERICAN AND CANADIAN PATENT COPPER DEPOSITING COMPANY (LIMITED).—Application has been made to the Stock Exchange

Digitized by Google

to appoint a special settling day in, and to grant a quotation to 44,788 priority shares in this Company.

ELMORE'S FRENCH PATENT COPPER DEPOSITING COMPANY (LIMITED).—It is stated that the letters of allotment of the Ten per Cent. Preference shares of this Company have been posted.

GREAT NORTHERN TELEGRAPH COMPANY.—The distribution of 7s. 2d. per £10 share, representing the final dividend for 1891, is now payable at the Company's bankers, Messrs. C. I. Hambro and Son, 70, Old Broad-street, London, E.C., against coupon No. 24. The traffic receipts of this Company for April, 1892, amounted to £20,000; and from January 1st to April 30th to £82,800. In the corresponding months of 1891 and 1890 the amounts were £88,000 and £81,800 respectively.

MESSRS. MIX AND GENEST (LIMITED).—At the annual meeting of the shareholders of this Company, recently held at Berlin, a dividend of 6 per cent. was declared.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended April 29, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,275.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the fortnight ending April 30, 1892, amounted to £2,669, as compared with £2,984 in the corresponding period of last year, a decrease of £315.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 730.—Vol. XXIX. FRIDAY, MAY 13, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

While wishing every success to the Central London Railway, and valuing the staunch advocacy of electric traction by Mr. Greathead, we regret to see that he, unlike the London County Council, does not think that it is desirable that the lines should be made capable of taking ordinary existing rolling stock. The South London line was, of course, an experiment. It was built with remarkable economy, and the small size of the tubes and carriages contributed, no doubt, to the low cost. But it seems a mistake to build anything that can be called a railway, or even that can be used as a railway, to any other gauge than the standard 4ft. 8½in., and to any dimensions that will prevent the use of ordinary rolling stock This country is not yet quite played out; and it is as rash to attempt to forecast the possible extensions and development of electric railways, and whether or no it may some day be desirable to make junctions, as it was when Brunel stuck to his broad gauge, little dreaming of the troubles that would arise, or of the huge expansion of the railway system which would be embarrassed. If the possibility of an invasion is a serious objection to the construction of the Channel tunnel that same objection applies to a break of gauge or other impediment to through traffic. The possibility of pouring an army through London in any direction seems to be worthy of some consideration.

The progress of the Metropolitan Electric Supply Company, now the leading electricity supply company in the United Kingdom, will be watched with considerable interest by electrical engineers in this country, the system adopted being fairly typical, and the area served an average one. At the present moment the Metropolitan Company has 1,000 customers upon its books and nearly 100,000 lamps connected to its mains; it has succeeded in paying a 2 per cent. dividend; and having annexed the huge district of Paddington, an annexation not originally contemplated, it proposes to meet the outlay involved by a debenture issue. The text of the Chairman's speech was patience; and in the case of the Metropolitan Company there seems a reasonable probability that this virtue will not be without its reward.

It is instructive to note how the difference of system and environment affects both the apportionment of capital outlay and the various items of annual expenditure in the case of two typical supply companies such as the St. James and Pall Mall and the Metropolitan. In the revenue account for 1891 there is only one item, namely, rent, rates and taxes, and miscellaneous charges, which bears the same percentage proportion, viz., 9·2, to the year's expenses of the two concerns. A comparatively lightly-loaded plant and a multiplicity of stations probably account for the generating expenses of the Metropolitan Company amounting to over 78 per cent. of its total annual outgoings, as against 65 per cent. in the case of the St. James Company. On the other hand, when we come to capital expenditure, the high-pressure system may fairly be credited with the fact that the Metropolitan Company's outlay on lands has been only £12,388, or 2·5 per cent. of its total capital expenditure, as against 21·4 per cent. for the St. James Company; similarly, the outlay on mains has been respectively 22 per cent. and 31·5 per cent. of the total. An engineer's report would have been a particularly interesting supplement to the report, on account of the great variety of plant used, and of districts supplied by this Company.

"The Strange Adventures of an Electric Current" might have formed the title of Major Cardew's recent reports upon certain cases of damage in the district of the St. James Company. The report, which will be found elsewhere, attaches great importance to the presence of pilot wires in the culverts, but the explanation does not seem to be quite satisfactory. One of the most difficult problems of continuous-current supply is to localise leaks and earths on the mains. The careful night inspection of water supply has effected a most important saving in several cases, but the water, at the worst, only ran away into the soil or the drains. It is very probable that more damage by electrolysis has been done by leaks on electric supply systems than has yet been discovered. A development of the night-testing system, in which various feeders, mains, and consumers are disconnected during the small hours, seems to be the best way of localising faults.

As Mr. Nikola Tesla, without giving any satisfactory explanation for so doing, survived, after placing himself in circuit with many thousands of volts, magazine writers and other irresponsible dishers-up of scientific trifles have asserted that if lower frequencies had been employed the genial lecturer would have been volatilised, deflagrated, or otherwise distinctly and permanently inconvenienced. High-pressure experiments are just now very much *à la mode*. Messrs.

Digitized by Google

Siemens Bros. and Messrs. Swinburne and Co. are day after day wasting the valuable time of Messrs. Simpson and Fox-Bourne and adding to the attractions of the Crystal Palace Exhibition; while at the Royal Society *conversazione*, Dr. Bottomley, Prof. J. Crookes, Prof. Oliver Lodge, Mr. Wimshurst, and Messrs. Pyke and Harris, exhibited high-pressure discharges in various forms.

Quite as attractive and popular as the phonograph, and, it may be added, with as little promise, at present, of scientific or commercial importance, high-pressure discharges round a sheet of glass and the illumination of vacuum tubes without wires promise to be indispensable at any afternoon party. That bugle-call and the other phonograms have indeed become rather stale, and interest might well be gathered round the 100,000-volt discharge, which is "fifty times greater than the current used for American executions, don't-you-know." When the pretty experiments begin to pall, say, at the close of the season, excitement might be revived by allowing fair sight-seers to touch one terminal of the coil, and when this fails to draw, they might be allowed to "take the whole current," as the engineer was wont to do when he grasped the 110-volt terminals of the Edison dynamo in the old plant at Holborn Viaduct.

Many of the Crystal Palace experiments really take a considerable amount of power, but it is time that the mystery surrounding the vacuum-tube lighting was dispelled. The *Electrical World* of New York has made the difficulties, such as they are, apparently greater than they were, by constructing four questions, which were propounded to various authorities, eminent and otherwise. Had the questions been carefully considered, they could hardly have failed to elicit something worth reading, but they seem to have emanated from some one who had never heard of impedance.

Messrs. Swinburne and Co. and others have forced one or two horse-power through vacuum tubes for a few seconds; that is one of the new experiments. Another is to cause vacuum tubes to glow when held in the hand. But no one has yet given any idea of the current in either case. The great, and perhaps only, defect of Mr. Tesla's lecture was the absence of any quantitative information. Returning to the method of electrical measurement adopted by Cavendish, who estimated the magnitude of discharges by the shock felt, there is no doubt that an ordinary schoolboy's vacuum tube, illuminated to a fair drawing-room or *conversazione* degree, takes less than one milliampere and probably not more than one-tenth of that current. Mr. L. Pyke estimates that each foot run of ¼in. tube takes about one watt. The measurement of small alternating currents is rather difficult, but we hope some one will give attention to it. Quantitative measurements of small alternating currents are greatly needed also to place medical work upon a sound basis.

In the opinion of more than one authority on dynamo construction, the alternate-current machines of the future are likely to be built on the inductor principle. There is, fortunately, no master patent. Mr. Mordey has suggested more than one form of rotating-keeper dynamo, Mr. Kingdon has built several, and Mr. Rankin-Kennedy has given considerable attention to the subject. The machine to which we alluded last week, and of which we now give further particulars, presents many of the advantages of the type. The chief difficulty of an electrical nature is the heating. The mechanical difficulty in the present example is the carrying of the inductors with sufficient rigidity. The clearance in inductor machines ought to be very small, the "*entrefer*" being a mere air-gap, and containing no copper. There seems to be a choice between the overhanging keepers of Messrs. Pyke and Harris, passing between opposing pole faces, or the simple drum of Mr. Kingdon, with pole faces ranged side by side, or a radial arrangement. The last would necessitate the use of thrust bearings. The Pyke and Harris machine might be duplicated, with inductors projecting on each side of a driving disc, but mechanical equilibrium would thus be attained at the cost of ventilation and armature resistance. In the absence of armature-winding and commutators, the mechanical construction is a simple engineering job. High-speed drums running with small clearance present little difficulty, and we hope to hear more of this type of dynamo.

Antwerp.—It is proposed to hold an International Exhibition in Antwerp in 1894.

Royal Society.—The Papers down for reading yesterday included one on "Transformers," by Prof. Perry.

India-rubber.—Steps are being taken to develop the resources of the Upper Congo in the matter of india-rubber.

The Works of Prof. Weber.—The Royal Society of Gottingen are going to publish the works of Prof. W. Weber.

Monte Video.—It is stated that application has been made to the Monte Video Municipal Board for authority to establish a new telephone company, with subterranean wires.

Personal.—Our Glasgow correspondent informs us that Mr. William Buchanan, B.Sc., Whit. Sch., has been appointed electrical engineer to the London Electric Supply Corporation, on the recommendation of Lord Kelvin.

Cable Interruptions.—The following lines are actually interrupted:—

	Date of interruption.
Siberian land-lines	7th May.
Bolama-Bissao Cable	23rd April.

The Electric Lighting of the International Horticultural Exhibition.—A reward of £100 is being offered to any person giving such information as will lead to the conviction of those who did wilful damage to the electrical appliances of this Exhibition on Saturday evening last.

Institute of Chemistry.—A Conference of the members of this Institute will be held at the rooms of the Chemical Society, Burlington House, at 3 p.m. on Monday, May 16th. The subject for discussion will be "The present Regulations with respect to the Admission of Fellows and Associates to the Institute."

Nottingham.—The Electric Lighting Committee of the Town Council have had under their consideration applications for the post of electrical engineer in Nottingham. The salary offered was £300 per annum. There were 147 applicants. The post has been offered to Mr. H. Talbot, engineer to the Chelsea Electricity Supply Company.

The Electric Lighting of the City.—The City of London Electric Lighting Company intimate that applications for supply

Digitized by Google

have become so numerous that they must limit, during the next twelve months, the number of connections. Preference will be given—1, to premises already wired; 2, to premises for which guarantees to take current have been signed.

Breslau.—The results of the first half-year's working of the Breslau central station show receipts amounting to £7,500, the expenditure, including the writing off of 6 per cent. of the capital outlay, being £6,250. The total capacity of the station is 14,000 lamps, and at present 10,800 are wired. An extension of the system is being proposed, water power being available close to the town.

Portsmouth.—The Corporation Electric Lighting Committee have decided to adopt, for the lighting of the streets, Swan-Edison lamps of 200 c.p., which will be placed at distances of about 50 yards. The existing gas columns, which stand about this distance apart, will be used for the new lamps in almost every case. The Clarence Esplanade, from one pier to the other, will be illuminated by Brockie-Pell arc lights.

The Proposed International Electrical Congress at Chicago.—The following are some of the European men of science who have consented to act on the Advisory Council of this Congress:—Lord Kelvin, Mr. W. H. Preece, Prof. W. E. Ayrton, F.R.S.; Lord Rayleigh, Prof. S. P. Thompson, Prof. E. Mascart, M. E. Hospitalier, Dr. Werner Siemens, Prof. H. von Helmholtz, Prof. Galileo Ferraris, Prof. E. Gerard, and Prof. A. Stoletow.

Electricity and Gas at the Vienna Town Hall.—During the year 1890-91 nearly 9½ million cubic feet of gas were consumed in this building, giving a little over 21 million candle-hours, which, at 4s. 6d. per thousand, comes to 0·4d. per 16 candles per hour. The electric light cost £933, and some 20,000 units (B.T.U.) were used, which, at 55 watts per 16-candle lamp, works out at 0·615d. per 16 candles per hour, as against 0·638d. for the previous year.

Smoke Prevention.—A test of the combined apparatus of Messrs. Greaves and Sennett as applied to steam boilers has, says *Industries*, been recently made. Mr. Greaves' invention consists of fireclay arches through which the combined gases and air are passed, and which becoming incandescent cause the smoke to be consumed. Mr. Sennett's principle is the induction of a low-pressure current of air by means of steam jets, and the two devices combined give a very good result.

Société Internationale des Électriciens.—The following gentlemen form the council of this society for the current year: President, M. L. Raymond, Director of the Ecole Supérieure de Télégraphie; vice-presidents, MM. Bouillhet and Potier; secretaries, MM. Sarcia and de la Touanne; members of council, MM. Abdank-Abakanowicz, Baille, Baudot, H. Becquerel, J. Boulanger, Brüll, Cance, Cornu, Fribourg, Friedel, Gaudry, Hillairet, Krebs, Meyer, Mildé, Raffard, Tripier, Vaschy, Violle, and Vlasto.

Crystal Palace Electrical Exhibition.—Popular experimental demonstrations are being given on Wednesday evenings at 8.30 in the theatre of the Palace by Dr. J. A. Fleming. The subject chosen by Dr. Fleming is "Electro-Magnets and Electric Currents: their Production and Use." Views are given by means of a large Brockie-Pell arc-light lantern, arranged by Mr. T. C. Hepworth. The first of these lectures was delivered on Wednesday evening last; others will be given on May 18, 26, and June 1.

Deputation to the Postmaster-General.—A large deputation from the Associated Chambers of Commerce will wait on the Postmaster General to-day, for the purpose of urging, among other things, the reduction of the inland registration fee to one penny, the extension of the postal order system to all Colonies and British Possessions, and the cheapening of telegrams by reduction of price, or by allowing addresses to be sent free. The deputation will also recommend that the Government should take over the telephone system, and that telegraph wires should be protected by being laid underground.

Montreal.—The Royal Electric Company of Montreal, says the *Electrical World*, has in contemplation some very important plans for increasing the capacity of its plant. The Company contemplates the utilisation of the Chambly Rapids, and as soon as the water is low enough operations are to be commenced. The rapids are susceptible of developing, it is estimated, at lowest water, over 20,000 H.P. Once the work is commenced it is to be carried on vigorously, and by the end of the present summer one-third of the power, it is expected, will be developed. It will probably be two years before the full power has been developed.

Aluminium.—A company has been formed in Philadelphia, says *Industries*, for the purpose of manufacturing aluminium by a new process discovered by Mr. Edward C. Broadwell. By this process, which is both electrolytic and chemical, it is claimed that 5,000lb. of aluminium can be made with the expenditure of 5,000 E.H.P.H. It is also claimed that the finished product can be sold at 15c. per pound, with a slight profit, which is about the same as the price of copper, and about one-fourth of the present price of aluminium. The Company is known as the American Aluminium Company, and has a capital of £400,000.

The Electrical Utilisation of Water Power.—An interesting hydro-electric power station is approaching completion between Herrenwiesen and Bülach. Three canals, two starting from the left and one from the right bank, have been dug. The first one on the left is 215 metres long, and will give from 380 to 400 H.P. under a head of 11 metres. This power is to be transmitted by electricity to the Oerlikon works, nine miles off. The second canal on this bank is 66 metres long, and also gives a fall of 11 metres. The third canal gives 70 H.P., which is to be electrically transmitted to Bülach and there supply power to some glass works, a saw mill, a flour mill, and a central lighting station.

Obituary.—We regret to have to record the death of Dr. James Thomson, brother of Lord Kelvin, and Emeritus Professor of Civil Engineering in Glasgow University. Prof. Thomson was born in Belfast in 1822, and chose the profession of a civil engineer, serving his apprenticeship in the works of the late Sir William Fairbairn. In 1857 he became Professor of Civil Engineering in Queen's College, Belfast. In 1872 he was elected to fill the Glasgow chair. Prof. Thomson maintained his zeal for scientific pursuits, and in March of this year he completed a Paper on the grand currents of atmospheric circulation, which was chosen by the Royal Society as Bakerian Lecture for the year.

The Dissipation of Heat in Armatures.—At a recent meeting of the Société Internationale des Électriciens, M. Rechniewski gave the results of some investigations by M. Labour and himself, on the relations between energy dissipation in and cooling surface of dynamo armatures. M. Rechniewski allows a raise of 50°C. above the temperature of the surrounding atmosphere. The figures he arrived at in the case of three 2-pole drum machines were 7·14, 6·9, and 7·5 sq. cms. per watt dissipated. With vigorous internal ventilation, only 4·25 sq. cms. need be allowed. Finally, in certain armatures of multipolar machines with open interiors and vigorous ventilation, M. Rechniewski concludes that 3·3 sq. cms. per watt dissipated will suffice.

A Bismuth Battery.—If two bismuth electrodes are plunged into a vessel containing a solution of bismuth-chloride, or of hydrochloric acid, and if one of the electrodes is placed between the poles of an excited electro-magnet, a galvanometer will show that an electric current flows in the liquid from the magnetic electrode. This current is always in the same direction. The electro-motive force varies with the electrodes and the solutions; in certain cases it may attain ·0023 Daniell when the magnetic field = 81500 H (H = horizontal component of the earth's field). This current, says G. P. Grimaldi in *Il Nuovo Cimento*, Vol. XXV., p. 191, is due partly to the motion of the diamagnetic liquid, which is caused by the magnetic field, and it also seems to depend on the peculiar effect which magnetism appears to have on the position of bismuth in the electro-contact series

Trolley Accident at Marseilles.—Just as the overhead trolley line at Marseilles, on which numerous experiments have lately been made, was about to come into regular operation, an

Digitized by Google

accident has occurred which will probably delay the matter some time. The conductors are carried on insulators which are hung from transverse iron wires attached to wooden posts on either side of the double track. In order to guard against the possibility of telephone wires making contact with the trolley line, the Government insisted on insulating forks being arranged so that protecting wires carried by their arms should run exactly over the trolley wires. The accident arose from the trolley "jumping" the line and striking against the guard wires, bringing a length down on to the "live" wires below, and on to a dog and a horse on the ground, with the result that these animals were killed by the 550-volt current.

The British South Africa Company's Telegraphs.—The extension of the British South Africa Company's telegraphs has been carried on under the direction from Cape Town of Mr. Stanford, the assistant superintendent of telegraphs, and offices have been opened at:—

	Date of opening. 1891.	Length of sections. Miles.
Macloutsie	13th May	89
Tuli	28th May	50
Nuanetsi	9th Sept.	97
Victoria	31st Oct.	71½
	1892.	
Charter	18th Jan.	110¼
Salisbury	16th Feb.	61½

This completes the construction work inaugurated by the Company in 1890—a total distance from Mafeking of 772¼ miles.

The Deptford Station.—"Through excess of zeal accompanied by lack of discretion, a hunter," says the *Electrical Engineer* of New York, "once upon a time found himself in the position of having an exceedingly lively tiger by the tail, and was thereupon confronted with the awful conundrum as to whether he would do worse to hold on or to let go. This appears to be be substantially the situation which now confronts the London Electric Supply Corporation, organised four years ago to produce and distribute electricity on a colossal scale, as if, like the brewing and sale of beer, it was simply a question of a sufficiency of working capital. . . . One cannot but admire the true Anglo-Saxon pluck with which the shareholders of this ill-starred undertaking have stood by their colours, and still stand by them. . . . One cannot but hope that the undertaking may be attended with at least a reasonable degree of success. Such splendid courage deserves a happier issue than has so far attended the venture."

Taunton.—A special meeting of the Town Council was held on Tuesday last week to receive and consider the report of Mr. Gisbert Kapp, who has been employed by the Council to make a valuation of the Taunton Electric Lighting Works, which the company owning them have offered to the Council for the sum of £10,000. Mr. Kapp reported that the present system (the Thomson-Houston) was not suitable for small areas. For various reasons he could not advise the Council to buy the undertaking as a going concern. Taunton could be lighted most economically on the direct-current low-pressure three-wire system, with batteries to take the day load. If they determined to utilise the existing station the Council could take over the buildings, boilers, engines, and accessories, and 44 iron posts, paying the company £5,250. The Council expressed an opinion greatly in favour of continuing the present system, and it was agreed that the consideration of Mr. Kapp's report should be postponed until the next meeting of the Council.

The Azores Cable.—The Lisbon correspondent of *The Times* writing under date May 10th, says, "To-day's *Diario* contains an announcement inviting tenders, to be handed in by the 25th inst., for the construction and working of cables from Lisbon to all the principal Azores Islands. Provision must also be made for the continuation of the cable to Flores Island and North or Central America, and also for constructing a cable from Lisbon to a point on the Continent of Europe. A provisional deposit of £10,000 must be made for the privilege of competing, besides one of £20,000 in the event of the tender being accepted. The scheme of construction is based principally on the clauses of the contract entered into last February between the Portuguese Government and the British Company; but it has apparently been modified so as considerably to facilitate a tender from the French syndicate, and I understand that in any case it does not admit of such advantageous terms for Portugal as those lately offered by the British Company. The matter appears to have an international importance."

Non-Arcing Metals.—In the course of some exhaustive investigations on lightning protectors, Mr. Alexander J. Wurts, of New York, lighted upon several combinations of non-arcing metals. Mr. Wurts's theory of the action of non-arcing metals is that a vapour of high resistance is momentarily projected between the poles, breaking the arc. In this connection Mr. McCay writes to the *Electrical Engineer* of New York, of April 13th, stating that while working several years ago in Berlin, under Prof. Helmholtz, he obtained the purest possible mercury and zinc, and made amalgams, and in every case found that they decreased in resistance. Mr. Wurts, in the Paper which he read before the American Institute of Electrical Engineers on March 15th last, said he found that the *paste* made from zinc and mercury was an arcing metal, while pure zinc and mercury were non-arcing. Mr. McCay considers this fact a striking corroboration of Mr. Wurts's hypothesis. The resistance of zinc and mercury both increase with the temperature; but as the electrical resistance of zinc-mercury amalgams does not follow the usual law of alloys, it is highly probable that the resistance *decreases* with high temperatures, and it would therefore follow, on Mr. Wurts's theory, that the paste would arc.

Electricity in Mining.—A meeting of the Association of Belgian Mining Engineers was held in Liége on the 7th inst., at the new Montefiore Electrical Institute. The chair was taken, in the unavoidable absence of M. Montefiore, by M. Dechamps, the President, who opened the proceedings by introducing to the meeting Mr. Llewelyn Atkinson, of London, and Mr. D. Selby Bigge, of Newcastle-on-Tyne. Mr. Walton Brown, Secretary of the North of England Mining Institute, who had hoped to be present, was prevented at the last moment from coming. After an interesting description by Prof. Eric Gerard of the Institute and its work, Mr. Selby Bigge read a Paper "L'Application de l'Électricité dans les Travaux des Mines." In the course of his lecture the author referred to the important question of safety in mines, and described the various precautions taken by Messrs. W. T. Goolden and Co. in the manufacture of their electric mining machinery, and by himself in the laying down of the same. The whole company present then visited the fine laboratories and workshops of the Institute. It is interesting to note that the whole of the internal wiring of the Institute is carried out by wires twisted together to avoid the influence of the current upon delicate instruments used.

An Electrolytic Experiment.—In *La Lumière Electrique* for March 19th the following electrolytic experiment is described: it is due to Herr Arons, and was shown by him to the Berlin Physical Society. If we place a hollow copper cylinder between the electrodes of a sulphate of copper voltameter, copper will be deposited on the cylinder where the current enters it, and dissolved where it leaves. If the cylinder is free to turn about a horizontal axis, it will commence to rotate as soon as the current passes, owing to the surface next the anode becoming weighted. It is possible to arrange matters so that the specific gravity of the cylinder is only a trifle greater than that of the solution, and hence the pressure of its axis upon the supports may be indefinitely reduced. The containing vessel used by Herr Arons was a glass box. The copper cylinder, which occupied nearly the entire width of the containing vessel, was 4·5cm. long, and 10cm. in diameter, and the walls were about 1·8mm. thick. The spindle was formed by a glass rod 1mm. in diameter, secured to ebonite plugs fixed into the cylinder; the spindle rested on ebonite supports, attached to the walls of the containing vessel. The cylinder turned slowly and continuously under the influence of currents varying from 0·1 to 1 ampere. Experiments showed that the speed of rotation was very nearly proportional to the current.

A Standard Condenser.—In the *Comptes Rendus* of March 21st, M. Abraham described a standard air-condenser constructed by him with a view to a fresh determination of *v*. The capacity was about 500 C.-G.-S. units (electrostatic). The plates consisted of two circular slabs of Saint-Gobain plate glass, 2·3cm. thick and 35cm. in diameter, both faces and all the edges being completely silvered over. The opposing faces were accurately planed. One of the plates rested on cloth pads, supported on paraffin supports. The silvered surface of the other disc having to be divided into a collecting plate and a guard-ring system, a circle 22cm. in diameter was cut in it by means of the steel burin of a circular dividing engine, a clean cut 0·1mm. broad being effected. This same plate was pierced at the centre with a hole 2·5mm. in diameter, widened out into a cone towards the planed surface. The interior of this cone was silvered, and its end stopped with an accurately-fitting silver plug, to which was soldered the wire connecting the condenser with the measuring instrument. The guard-ring plate was separated from the other plate by three accurately-turned quartz washers, arranged to come underneath the guard-ring. The insulation afforded by the quartz washers was found to be excellent. The insulation resistance of the groove cut in the plate was over 80,000 megohms. With the width adopted for the guard-ring (6·5cm.) the correction for edge influence was less than $\frac{1}{30000}$th, even when the plates were 1cm. apart. The linear dimensions of the condenser were all measured by a standard dividing engine.

Telegraphic Communication with Lighthouses and Lightships.—In the course of his Paper on "Electricity in the Navy," read last week before the United Service Institution, Lieutenant F. T. Hamilton said that one use of the telegraph that we were at present hearing a great deal about was for communication with outlying lighthouses and lightships. There were two difficulties in the way. A plan had, however, been devised by the Telegraph Construction and Maintenance Company, by which communication could be made to both lighthouses and lightships without the cable actually going on board them. A twin cable was led out from the shore to within a quarter of a mile of the lighthouses or ship. The cores were then forked out, and ended in large earth plates about a quarter of a mile apart, one on either side of the place to be telegraphed to. Two earth plates were put overboard, one from either end of the lightship, or on either side of the lighthouse. If Morse signals were now sent along the twin cable from the shore they could be distinctly heard in a telephone on board the lightship. The plan was under trial, and was likely to get over the difficulty of communication. But the second difficulty was not so easily disposed of. At present lighthouses and lightships were supposed to be exempt from attack in war time, but if we had telegraphs to them it would be a sore temptation to use them as outlying signal stations for reporting the enemy's movements; and even if our morality were proof against the temptation, what enemy was going to give us credit for such correct behaviour?

The Utilisation of Wind-Power.—In an article on this subject in *La Lumière Electrique*, M. G. Pellissier points out that we obtain far more mechanical power from the movements of the atmosphere than is generally supposed. For instance, last year the tonnage of the sailing fleet of the world amounted to four and twenty millions, and to these vessels must be added the thousands of windmills at work in Europe and America. Nevertheless, many long-established windmills have been and are being replaced by steam power, and the few instances of the application of wind-power to dynamo-driving have not proved economically encouraging. The main cause of this is the great irregularity of aerial currents both in direction and velocity. Recent experiments at the top of the Eiffel Tower have, however, shown that at moderate altitudes these irregularities tend to disappear. In Vol. XXXVIII. of the *Annuaire de la Société Météorologique de France* M. Angot publishes the results of observations made simultaneously at the top of the Eiffel Tower (305 metres) and at the Bureau Central Météorologique (500 metres distant from the tower) at an altitude of 20 metres. Figures given by M. Angot show that the speed of the wind at a height of 305 metres is on the average some three times as great as it is at an altitude of 20 metres, its direction being at the same time more constant. Considerable advantages, therefore, accrue from placing windmills at moderate altitudes. At the meeting of the British Association at York in 1881 Sir William Thomson discussed the subject of the utilisation of wind-power, and came to the conclusion that so far, at any rate, as its electrical utilisation was concerned the thing was out of the question by reason of the high prime cost and poor efficiency of the windmill. This conclusion has been traversed by a Mr. A. R. Wolff, who is of opinion that the windmill is the most economical of all prime motors where small powers are to be dealt with; the impossibility of the extensive electrical utilisation of wind-power being, according to him, due solely to the poor quality of the modern accumulator. However this may be, says M. Pellissier, coal is destined to disappear, and the utilisation of wind-power becomes daily more important.

Royal Society Selected Candidates.—Among the 15 candidates selected on Thursday, May 5th, by the Council of the Royal Society, to be recommended for election into the Society on June 2nd, we note the names of Dr. J. A. Fleming, Mr. J. Larmor, and Lieut.-Col. R. Y. Armstrong, R.E. The following are the statements of the qualifications of these candidates:—John Ambrose Fleming, M.A. (Camb.), D.Sc. (Lond.). Prof. of Electrical Engineering in University College, London. Late Fellow of St. John's College, Cambridge. Fellow of University College, London. Some time Demonstrator in Applied Mechanics in the University of Cambridge. Author of the following Papers, among others:—"The Polarisation of Electrodes in Water free from Air" (*Proc.* Phys. Soc., 1874); "A New Form of Resistance Balance" (*Proc.* Phys. Soc., 1880); "On the Characteristic Curves and Surfaces of Incandescent Lamps;" "On Molecular Shadows in Incandescent Lamps;" "On the Use of Daniell's Cell as a Standard of Electro-Motive Force;" and "Problems in the Distribution of Electric Currents in Networks of Conductors" (*Proc.* Phys. Soc., 1885); "On the Necessity for a National Standardising Laboratory for Electrical Instruments" (*Proc.* Inst. Elect. Engs., 1885); "A Design for a Standard of Electrical Resistance" (*Proc.* Phys. Soc., 1889); "On Electric Discharge between Electrodes at Different Temperatures in Air and in High Vacua" (*Proc.* Roy. Soc., 1889; "On Some Effects of Alternating-Current Flow in Circuits having Capacity and Self-Induction" (*Proc.* Inst. Elect. Engs., 1891). Delivered Friday Evening Discourses at the Royal Institution, 1890-91. Author of "Short Lectures to Electrical Artisans," four editions, and of "The Alternate-Current Transformer in Theory and Practice."—Robert Young Armstrong, Lieut.-Colonel R.E., from 1870 to 1875 was Assistant-Instructor in Submarine Mining and Electricity, and from 1875 to 1882 was Instructor. From 1884 to the present date, Inspector of Submarine Defences of the United Kingdom, Military Ports, and Coaling Stations. From June, 1883, to December, 1888, adviser to the Board of Trade in electrical matters connected with the Electric Lighting Acts. Was connected with the development of the present apparatus and electrical and mechanical processes employed in submarine mining, and with the compilation of the Army instructional books and methods on electricity and submarine mining since 1870. Distinguished as an electrical engineer. It may be said that the present satisfactory state of defensive torpedo warfare in this country is very largely due to his ability and energy.—Joseph Larmor, M.A., D.Sc. Fellow of St. John's College, Cambridge. University and College Lecturer in Mathematics. Senior Wrangler, 1880. Formerly Professor of Mathematics Queen's College, Galway. Fellow of the Royal University of Ireland. Examiner in Mathematics at the University of London. ELECTROMAGNETIC THEORY.—XXVIII.

BY OLIVER HEAVISIDE.

(*Continued from page 598, Vol. XXVIII.*)

§ 133. The last equation brings us to the theory of potentials. There are several senses in which the word potential has been employed, to enumerate which would be valueless here. For our present purpose we may conveniently fix its meaning by defining the potential at A of a quantity ρ at B to be the quantity $\rho/4\pi r$, where r is the distance from B to A. This is the rational potential, of course.

When ρ is distributed throughout space, whether at points, or over surfaces, or throughout volumes, the potential at any point is the sum of the potentials of all the elements of ρ. That is,

$$\mathrm{P} = \text{pot}\,\rho = \Sigma\,\rho/4\pi r, \quad . \quad . \quad . \quad . \quad (195)$$

if P is the potential of ρ.

We may use the same definition when it is a vector that has to be potted, or potentialised. Thus, if $\mathbf{A}$ is the potential of $\mathbf{C}$, then

$$\mathbf{A} = \text{pot}\,\mathbf{C} = \Sigma\mathbf{C}/4\pi r. \quad . \quad . \quad . \quad . \quad (196)$$

The summation is now a vector summation. Also, pot means "potential," or "the potential of," and has no more to do with kettle than the trigonometrical sin has to do with the unmentionable one. It seems unnecessary to say so, but one cannot be too particular.

We may connect these potentials with ∇ as follows:—Given that

$$\text{div}\,\mathbf{F} = \rho, \quad . \quad . \quad . \quad . \quad . \quad (197)$$

that is to say, that the divergence of a vector $\mathbf{F}$ is ρ. The meaning of divergence has been explained more than once; both its intrinsic and its vectorial meaning. Now, if the vector $\mathbf{F}$ be explicitly given, it is clear that ρ is known definitely, since it is derived from $\mathbf{F}$ by differentiation, which should, perhaps, be regarded as a direct process, rather than inverse. But if it be ρ that is given, $\mathbf{F}$ is not immediately determinable, unless we subject $\mathbf{F}$ to limitations. For we may construct any number of different $\mathbf{F}$'s to satisfy (197). Let every elementary source ρ of $\mathbf{F}$ send out the quantity ρ of $\mathbf{F}$, according to my rational theory of sources already explained; that is, the unitarian system of *one* "line of force" to the *unit* "pole." Then, by the manner of construction, the resultant $\mathbf{F}$ will satisfy (197), and it will do so independently of the way we choose to let a source send out the flux it generates, whether equably or not.

But if it be done equally in all directions, so that $\rho/4\pi r^2$ is the intensity of the "force" at distance r from the point-source ρ, and $\mathbf{r}_1\rho/4\pi r^2$ the vector force to correspond, where $\mathbf{r}_1$ is a unit vector drawn from ρ towards the point under consideration, making the resultant $\mathbf{F}$ be

$$\mathbf{F} = \Sigma(\rho/4\pi r^2)\mathbf{r}_1, \quad . \quad . \quad . \quad . \quad . \quad (198)$$

we obtain a special solution of (197) which has a remarkable property, viz.,

$$\text{curl}\,\mathbf{F} = 0, \quad . \quad . \quad . \quad . \quad . \quad (199)$$

so that if $\mathbf{F}$ be electric force, the voltage in any circuit is zero. The meaning of curl, I may observe, has been explained more than once; both its intrinsic and its vectorial meaning. Those who seek can find. If they will not take the trouble to seek or to remember it is of no consequence to them. There are plenty of other things they may concern themselves about; perhaps more profitably.

The property (199) is visibly true in the case of a single source. It is therefore separately true for the fields of all the sources, and therefore, by summation, is true for the complete $\mathbf{F}$.

But (198) does not give the only vector which has no curl and a given divergence. For a constant vector (that is, constant throughout all space), has no curl and no divergence, unless we go to the very end of space to find the sources. Of course this constant solution has no relation to the sources ρ, and may be wholly ignored. If allowed, $\mathbf{F}$ would not vanish at an infinite distance from the sources. Remembering this, and excluding the constant solution, we may say that (198) is *the* solution of (197) and (199).

That there is no other solution may be proved analytically by Green's Theorem. But we do not really need any appeal to analysis of that kind, if the intrinsic meanings of divergence and curl are understood. For the admission that there could be a second solution, say, $\mathbf{F}+\mathbf{f}$, where $\mathbf{F}$ is the solution (198), would, by (197) and (199), imply that the vector $\mathbf{f}$ had no divergence, and also no curl anywhere. But the first of these conditions means that $\mathbf{f}$ is entirely circuital, if existent at all. The second denies that it is circuital. So $\mathbf{f}$ is non-existent.

Now observe that

$$-\nabla\,(1/4\pi r) = \mathbf{r}_1/4\pi r^2,$$

or the slope of the scalar $1/4\pi r$ is the vector with tensor $1/4\pi r^2$ and direction $\mathbf{r}_1$. It follows from this that

$$-\nabla\,\text{pot}\,\rho = \mathbf{F}, \quad . \quad . \quad . \quad . \quad . \quad (200)$$

when a single point-source is in question. Therefore, by summation, the same is true for any distribution of sources, or

$$\mathbf{F} = -\nabla\mathrm{P} = -\nabla\,\text{pot}\,\rho, \quad . \quad . \quad . \quad . \quad (201)$$

where P is the potential of ρ, as defined by (195), and $\mathbf{F}$ is as in (198). The slope of P, if by this we understand slope downwards, or vector rate of fastest decrease, is therefore the same vector as was constructed to solve (197) subject to (199).

Taking the divergence of (201), we have, by (197) and (194),

$$\rho = \text{div}\,\mathbf{F} = -\nabla^2\mathrm{P} = -\nabla^2\,\text{pot}\,\rho. \quad . \quad . \quad . \quad (202)$$

A solution of the characteristic equation of P, or

$$\nabla^2\mathrm{P} = -\rho, \quad . \quad . \quad . \quad . \quad . \quad (203)$$

is therefore (195), and it is *the* solution vanishing at an infinite distance from the sources.

If we start from (203), we should first use (194), and make it

$$\text{div}\,(-\nabla\mathrm{P}) = \rho. \quad . \quad . \quad . \quad . \quad . \quad (204)$$

Then, by (190), we see that $-\nabla\mathrm{P}$ has no curl, so that we have again the two equations (197), (199) to consider, as above.

The consideration of $\mathbf{F}$ rather than of P has many advantages for purposes of reasoning, as distinguished from calculation. This is true even in statical problems; for instance, when $\mathbf{F}$ is electrostatic force, and P the corresponding potential. When we proceed further, to kinetic problems, when $\mathbf{F}$ can no longer be wholly expressed as the slope of a potential, the utility of considering P at all, even for calculating purposes, becomes sometimes very questionable, and sometimes certainly useless and misleading.

From (202) we see that $-\nabla^{-2}$ and pot are reciprocal. In another form, $-\nabla^{-2}$ and pot are equivalent; or $(\text{pot})^{-1}$ and $-\nabla^2$ are equivalent. The property has only been proved for a scalar function, having a scalar potential. But since any vector $\mathbf{C}$ may be written $\mathbf{i}C_1+\mathbf{j}C_2+\mathbf{k}C_3$, and the property is true for the three scalars C_1, &c., it is also true for the vector $\mathbf{C}$. Thus, explicitly,

$$-\nabla^2\,\text{pot}\,\mathbf{C} = -\nabla^2\,\text{pot}\,(\mathbf{i}C_1+\mathbf{j}C_2+\mathbf{k}C_3)$$
$$= \mathbf{i}\,(-\nabla^2\,\text{pot}\,C_1)+\mathbf{j}\,(-\nabla^2\,\text{pot}\,C_2)+\mathbf{k}\,(-\nabla^2\,\text{pot}\,C_3),$$

because the reference vectors $\mathbf{i}$, &c., are constant vectors. So, if A_1 is the potential of C_1, A_2 of C_2, and A_3 of C_3, which makes $\mathbf{A}$ be the potential of $\mathbf{C}$, according to (196), we shall have

$$\mathbf{A} = \text{pot}\,\mathbf{C}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (205)$$
$$-\nabla^2\mathbf{A} = \mathbf{C}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (206)$$
$$-\nabla^2\,\text{pot}\,\mathbf{C} = \mathbf{C}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (207)$$

In short, the characteristic equation of the vector $\mathbf{A}$ merely unites, from the above point of view, the characteristics of the components, so that pot and $-\nabla^2$ are reciprocal when the operand is a vector, as well as when it is a scalar.

§ 134. But the above gives a very partial and imperfect view of the general theory of potentials. There are numerous other relations between a vector and its associated functions. For instance, if in (206), $\mathbf{A}$ be circuital, then the Laplacean ∇^2 may, by (193), be replaced by $-(\text{curl})^2$. That is, if $\mathbf{A}_1$ be circuital, and be the potential of $\mathbf{C}_1$, then,

$$\text{curl}^2\,\mathbf{A}_1 = \mathbf{C}_1, \quad . \quad . \quad . \quad . \quad (208)$$

or

$$\text{curl}^2\,\text{pot}\,\mathbf{C}_1 = \mathbf{C}_1. \quad . \quad . \quad . \quad . \quad (209)$$

Digitized by Google

Here, then, we have replaced the scalar operation $-\nabla^2$ by the vector operation curl done twice. Of course, $\mathbf{C}_1$ is also circuital, as is proved by (189).

Again, let the $\mathbf{A}$ of (206) be polar, or wholly divergent, and be now called $\mathbf{A}_2$, the potential of $\mathbf{C}_2$; then, by (193), we shall have

$$-\nabla \operatorname{div} \mathbf{A}_2 = \mathbf{C}_2, \quad . \quad . \quad . \quad . \quad (210)$$

or

$$-\nabla \operatorname{div} \operatorname{pot} \mathbf{C}_2 = \mathbf{C}_2 \quad . \quad . \quad . \quad . \quad (211)$$

Here again we have replaced ∇^2 by a double operation, first div and then ∇. This is similar to the passage from (203) to (204), only done in the reverse manner. In (210), by (190), $\mathbf{C}_2$ is polar, because $\mathbf{A}_2$ is.

Conversely, we see that the potential of a circuital vector is also circuital, and that the potential of a polar vector is also polar.

Now $\mathbf{A}_1$ has no divergence, so it may be added on to the divergent $\mathbf{A}_2$ in (210) without affecting its truth. Thus, if $\mathbf{A} = \mathbf{A}_1 + \mathbf{A}_2$, we have

$$-\nabla \operatorname{div} \mathbf{A} = \mathbf{C}_2. \quad . \quad . \quad . \quad . \quad (212)$$

Similarly, $\mathbf{A}_2$ has no curl, so may be added to the $\mathbf{A}_1$ in (208), giving

$$\operatorname{curl}^2 \mathbf{A} = \mathbf{C}_1. \quad . \quad . \quad . \quad . \quad . \quad (213)$$

Here remember that $\mathbf{A}$ is the potential of $\mathbf{C}$ or $\mathbf{C}_1 + \mathbf{C}_2$.

These equations supply one way of effecting the division of a vector $\mathbf{A}$ of general type (having both curl and divergence) into two vectors, one of which, $\mathbf{A}_1$, is circuital, whilst the other $\mathbf{A}_2$ is polar. For $\mathbf{A}_2$ is the potential of $\mathbf{C}_2$, so, by (212),

$$-\operatorname{pot} \nabla \operatorname{div} \mathbf{A} = \mathbf{A}_2 \quad . \quad . \quad . \quad . \quad (214)$$

separates $\mathbf{A}_2$ from $\mathbf{A}$. Similarly, $\mathbf{A}_1$ is the potential of $\mathbf{C}_1$, so by (213),

$$\operatorname{pot} \operatorname{curl}^2 \mathbf{A} = \mathbf{A}_1 \quad . \quad . \quad . \quad . \quad (215)$$

separates $\mathbf{A}_1$ from $\mathbf{A}$, and therefore $\mathbf{A}_2$ from $\mathbf{A}$ by a different method. There are many other ways of splitting $\mathbf{A}$ into circuital and divergent parts. The one most easily understood, apart from the mathematics, is the following. Go over the whole field of $\mathbf{A}$ and measure its divergence. If we find that there is no divergence, then we do not need to go further, for we know that $\mathbf{A}$ is circuital already; that is, $\mathbf{A} = \mathbf{A}_1$, and $\mathbf{A}_2 = 0$. But should there be divergence, say B_2, so that

$$\operatorname{div} \mathbf{A} = \operatorname{div} \mathbf{A}_2 = \mathrm{B}_2, \quad . \quad . \quad . \quad . \quad (216)$$

then construct the flux $\mathbf{A}_2$ corresponding to the divergence B_2 according to the method already explained with respect to (197); thus,

$$\mathbf{A}_2 = \Sigma(\mathrm{B}_2/4\pi r^2)\mathbf{r}_1 = -\nabla \operatorname{pot} \mathrm{B}_2, \quad . \quad . \quad . \quad . \quad . \quad (217)$$

by (198) and (200). Knowing $\mathbf{A}_2$, we know $\mathbf{A}_1$, or $\mathbf{A} - \mathbf{A}_2$.

Or we might vary the process thus. First measure the curl of $\mathbf{A}$. This is the same as the curl of $\mathbf{A}_1$ because the curl of $\mathbf{A}_2$ is zero. Let, then,

$$\operatorname{curl} \mathbf{A} = \operatorname{curl} \mathbf{A}_1 = \mathbf{B}_1, \quad . \quad . \quad . \quad . \quad (218)$$

and construct the circuital solution of this equation; that is to say, regarding $\mathbf{B}_1$ as given, find $\mathbf{A}_1$. It is given by

$$\mathbf{A}_1 = \operatorname{curl} \operatorname{pot} \mathbf{B}_1. \quad . \quad . \quad . \quad . \quad (219)$$

For $\mathbf{A}_1$ as thus defined is evidently circuital, in the first place; and next, by taking the curl, we produce

$$\operatorname{curl} \mathbf{A}_1 = \operatorname{curl}^2 \operatorname{pot} \mathbf{B}_1 = \mathbf{B}_1, \quad . \quad . \quad . \quad (220)$$

which is the given datum. Here we use $\operatorname{curl}^2 \operatorname{pot} = 1$, because the operand is circuital, as in (209).

But instead of (219) we may write

$$\mathbf{A}_1 = \operatorname{pot} \operatorname{curl} \mathbf{B}_1, \quad . \quad . \quad . \quad . \quad (221)$$

showing an entirely different way of going from $\mathbf{B}_1$ to $\mathbf{A}_1$. For $\mathbf{A}_1$ as thus constructed is circuital; and, since $\operatorname{curl} \mathbf{B}_1 = \mathbf{C}_1$, (221) is the same as

$$\mathbf{A}_1 = \operatorname{pot} \mathbf{C}_1,$$

which was our definition of $\mathbf{A}_1$ in terms of $\mathbf{C}_1$.

Thus pot curl and curl pot are equivalent when the operand is circuital, as above. They are, however, also equivalent when the operand is general, or both circuital and divergent, because if any divergent vector be added to the $\mathbf{B}_1$ in the right members of (219) or (221), the operation of curl to which it is subjected renders its introduction inoperative. We therefore have

$$\operatorname{pot} \operatorname{curl} \mathbf{C} = \operatorname{curl} \operatorname{pot} \mathbf{C}, \quad . \quad . \quad . \quad . \quad (222)$$

where $\mathbf{C}$ is any vector. We have also the similar exchangeability,

$$\operatorname{pot} \operatorname{curl}^2 \mathbf{C} = \operatorname{curl}^2 \operatorname{pot} \mathbf{C}, \quad . \quad . \quad . \quad . \quad (223)$$

where $\mathbf{C}$ is any vector. For, either way, the result is the circuital part of $\mathbf{C}$, or $\mathbf{C}_1$.

These results, though puzzling at first from their variety, are yet capable of being brought under rapid mental control by bringing them together in a compact form. Thus, start with any circuital vector $\mathbf{A}_1$. Let $\mathbf{B}_1 = \operatorname{curl} \mathbf{A}_1$, $\mathbf{C}_1 = \operatorname{curl} \mathbf{B}_1$, $\mathbf{D}_1 = \operatorname{curl} \mathbf{C}_1$, &c. We have a series of vectors

$$\mathbf{A}_1, \quad \mathbf{B}_1, \quad \mathbf{C}_1, \quad \mathbf{D}_1, \quad \mathbf{E}_1, \quad . \quad . \quad .$$

which are all circuital, and any one of which is the curl of the preceding. We thus pass down the series one step at a time by means of the operation of curling; for example,

$$\mathbf{D}_1 = \operatorname{curl} \mathbf{C}_1. \quad . \quad . \quad . \quad . \quad . \quad . \quad (224)$$

If, however, we wish to go down two steps, we do not need to go first one step, as above, and then another, also as above; but can make a double step in one operation by means of the Laplacean ∇^2. Thus,

$$-\nabla^2 \mathbf{B}_1 = \mathbf{D}_1. \quad . \quad . \quad . \quad . \quad . \quad (225)$$

Now go the other way. If we wish to rise up two steps, we can do it in one operation by potting; thus,

$$\mathbf{B}_1 = \operatorname{pot} \mathbf{D}_1. \quad . \quad . \quad . \quad . \quad . \quad (226)$$

If we wish to go up only one step, we may do it by (224), (225), (226) combined; that is, either go down one step first, and then up two, as in

$$\mathbf{B}_1 = \operatorname{pot} \mathbf{D}_1 = \operatorname{pot} \operatorname{curl} \mathbf{C}_1; \quad . \quad . \quad . \quad (227)$$

or else, first go up two steps and down one; thus,

$$\mathbf{B}_1 = \operatorname{curl} \mathbf{A}_1 = \operatorname{curl} \operatorname{pot} \mathbf{C}_1. \quad . \quad . \quad . \quad (228)$$

There are other less important combinations. But if we wish to make one step up directly, without making use of the double step, we must do it by the Ampèrean formula, already used, whereby we pass direct from electric current to its magnetic force, which, in rational units, is (when applied to any pair of neighbours $\mathbf{C}$ and $\mathbf{D}$ in the above series),

$$\mathbf{C} = \Sigma(\mathbf{V}\mathbf{D}\mathbf{r}_1)/4\pi r^2, \quad . \quad . \quad . \quad . \quad (229)$$

where $\mathbf{r}_1$ is a unit vetor from the element $\mathbf{D}$ to the point at distance r therefrom, where $\mathbf{C}$ is reckoned. We have now a complete scheme, so far as the circuital vectors are concerned.

(To be continued.)

A MODEL OF THE ELECTRIC ORGAN OF THE RAIA TORPEDO.

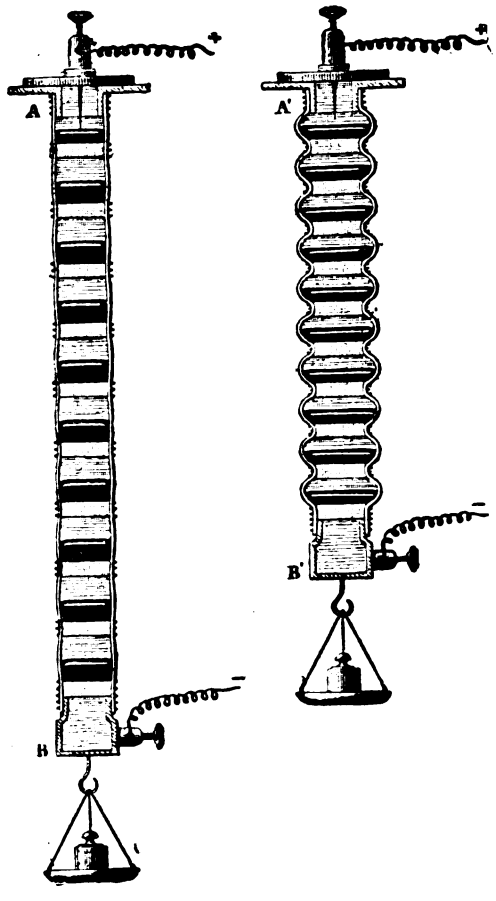
In the course of some articles in *La Lumière Electrique*, entitled "The Generation of Electricity by Living Beings," M. d'Arsonval discusses the nature of the source of the electric supply in animals such as the *gymnotus electricus* and the *Raia Torpedo*. The electrical apparatus of the *gymnotus*, says M. d'Arsonval, is situated underneath the animal, the positive pole being at its head, the negative at its tail. In order to give violent shocks and stun its prey at the first blow, the *gymnotus* folds itself into a circle, and completes the electric circuit through the body of the doomed animal. At the Collège de France M. d'Arsonval possesses a *gymnotus* which can give high-pressure discharges sufficiently powerful to magnetise electro-magnets. The maximum pressure is more than 100 volts, and the maximum current is probably 2 amperes. In the case of the *gymnotus* the discharge is continuous and unidirectional. In the case of the *torpedo* it is not so. Some people, says M. d'Arsonval, liken these electrical organs to voltaic batteries or Leyden jars, but such analogies will not bear examination. If such were the case it would only be necessary to connect the poles for a discharge to take place. Now, it is erroneous to state that the *torpedo* invariably gives a shock when touched. If you

Digitized by Google

touch without irritating, nothing comes of it. Will governs the phenomenon. The electricity is not, so to speak, ready within the organs of electric fish; it is only generated when the animal wishes.

M. Lippmann has shown that an electric current can be generated in the following manner: Take two test tubes, place a layer of mercury in each, pour water on the top of the mercury, and connect the two vessels by a cotton wick dipping into the water. On inclining the tubes a current is produced in one direction, and on bringing them back to the vertical an inverse current is observable. The phenomenon is due to variations of capillarity.

These conditions are reproduced by protoplasmic matter. If we excite the protoplasm it alters shape and becomes a ball, and this deformation is accompanied by a negative variation, the surrounding liquid being positive. We thus have an electric current generated, bearing some proportion to the number of cellules.



It is easy, says M. d'Arsonval, to reproduce this experimentally. In the accompanying illustration a number of layers of mercury and water are shown superposed one on the top of the other in an india-rubber tube. If we stretch the tube we get an electric current. If we have several thousands of such cells, and if each gives an electromotive force of only one-third of a volt, a very high potential difference is soon obtained. Here we have the reason why these organs are voluntary organs, and only generate electric currents under the influence of the animal's will.

THE DISTRIBUTION AND MEASUREMENT OF ILLUMINATION.*

BY ALEX. P. TROTTER, B.A., ASSOC.M.INST.C.E.

This Paper was divided into three sections. The first dealt with geometrical principles, the second with photometers, and the third with the results of measurements made in the streets and public buildings in London.

When light falls upon a surface, that surface is said to be illuminated. Illumination consists of two factors—candle-power and distance.

* Abstract of Paper read before the Institution of Civil Engineers, May 10, 1892.

The carcel-meter was proposed in 1882 as a unit of illumination. Mr. Preece showed that this was equal to a standard candle at 12·7in., and proposed the name "Lux" for the English equivalent. The author has taken the candle-foot as a practical unit. The illumination of a horizontal plane at any point varies as the cube of the cosine of the angle of incidence of a ray of light falling on that point, when the candle-power and the height of the lamp are constant. Curves were given, showing this distribution graphically; illumination being represented as ordinates, and distances from the source of light as abscissæ.

The distribution of the total light on a surface varies as the solid angle subtended by that surface at the source of light. The usefulness of a white reflector depends on the solid angle which it subtends, and not upon its absolute dimensions. The resultant illumination, due to a number of lamps spaced at distances apart, equal to once, twice, three times, and six times their height from the ground, was shown by a number of curves. The distribution of the light of a continuous-current arc lamp is peculiar. For angles of incidence greater than 50deg. it varies as the fourth power of the cube of the cosine of the angle of incidence. Light falling in a more vertical direction is largely reduced by the shadow of the negative carbon.

The object of street lighting is twofold—to mark out the street with beacons, and to provide illumination. Illumination begins to be useful when it is comparable with moonlight. Moonlight in this country rarely exceeds one thirty-sixth of a candle-foot, that is, a candle at 6ft.; it is generally between one-sixtieth to one-hundredth of a candle-foot. The distribution of illumination in more general cases was treated geometrically; the variation of illumination due to the varying height of a lamp was discussed, and it was shown that there was no particular virtue in the angle of incidence, the tangent of which is $\sqrt{2}$.

Calculated contour curves of equal illumination, due to two lights at a distance apart equal to three times their height, and to three lights arranged in a triangle, at a distance apart equal to one and a-half times their height, were given, together with curves of illumination due to arc lights spaced in a similar manner. The use of diagrams to which the author gave the name of characteristic curves was explained. In several respects these resembled steam-engine diagrams. The co-ordinates were candle-power and area; the area of the diagram was a measure of total light, or power in an optical form. The maximum and minimum illuminations in any example could be seen at a glance, and the shape of the curve showed the quality or regularity of the distribution. Characteristics for a square and for a circular area illuminated by a single light, and for several arrangements of uniformly spaced lights, were given.

The second section on photometry alluded to the different attempts which have been made to supplant photometers by thermopiles, radiometers, and photographic methods. The complication of gas-testing apparatus was contrasted with the simple forms of true photometers, such as those of Bunsen, Rumford, and Foucault. A photometer was described, in which a shadow was thrown by a mirror upon a screen and a reflected beam of light was superposed upon the shadow; the whole screen was of a uniform tone when a balance was effected. In a direct-reading photometer, a rod was placed nearly in the plane of the two lights to be compared. Two shadows were thrown on a screen, and the position at which the two shadows were of the same tone could be read off on a scale. The illumination photometers of Weber and Mascart were briefly described. Mr. Preece's photometer of 1883 depended on the measurement of the current of a small glow lamp. The sixth power of the current was approximately proportional to the candle-power. The current was adjusted by resistances. The details of this photometer were discussed, and Captain Abney's method of rapid oscillations in photometric measurement was described. Various errors were introduced in this use of a Bunsen screen and by the colour of the electric lamp at low candle-power In a photometer designed by the author, in conjunction with Mr. Preece, in 1884, a glow lamp was made to approach or to recede from a Bunsen screen. The motion was given by a lever rolling on a cam in such a manner that the illumination could be read upon a uniformly divided scale. A number of modifications of this photometer were tried during the past winter, and resulted in the construction of an illumination photometer with which a large number of measurements had been made. Two glow lamps, ¾ and ½-c.p., were mounted in a long, blackened box. Either or both could be used at once. Four lithanode cells supplied the current. A reflecting screen covered with white paper threw the light upwards through a star-shaped hole in a horizontal screen of cardboard. The reflecting screen was mounted on hinges and could be wound up by a fine chain, finally folding quite out of the light. The chain was wound upon a cam, and a hand or pointer was mounted on the axis of this cam. The cam was so shaped that a nearly uniformly divided scale was obtained. The scale was graduated empirically. Readings were taken when the illumination of the horizontal cardboard screen appeared to be identical with the illumination of the movable reflecting screen, visible through

Digitized by Google

the star-shaped hole. The range of this photometer is from 2·5 to 0·001 candle foot.

Measurements were made in the South Kensington Museum, in which illumination of about half a candle-foot up to 3½ candle-feet were recorded. In Cannon-street Station the minimum was 0·025 candle-foot, and the maximum 0·4 candle-foot. In Charing-cross Station the minimum was 0·05, and the maximum 0·5. Several sets of measurements were made in the City. The result of systematic measurement of part of Queen Victoria-street was given in contour lines of equal illumination. The maximum in an exceptional case was 1·1, ordinary maximum 0·3, minimum 0·025. Contour lines were constructed from a considerable number of measurements in Whitehall. The illumination in Great George-street, Westminster, was also measured. The maximum was 0·9, and the minimum 0·005. The author was assisted in the street measurements by Mr. W. Winny and by Messrs. J. Leggat, L. E. Pierce, and W. O. Wallace, students at Finsbury Technical College. Characteristic curves were drawn from these observations, and enabled the degree and the quality of the lighting to be compared. The Paper was accompanied by an Appendix, containing tables of the value of a bougie-meter in candle-power at different distances, values of $\cos.^3\theta$, and other powers of the cosine.

THE NATIONAL TELEPHONE COMPANY AND ITS SHEFFIELD SUBSCRIBERS.

A meeting of subscribers to the National Telephone Company in Sheffield was held on Monday last, at the Cutlers' Hall, to protest against the recent revised tariff. The Master Cutler (Mr. R. Belfitt) presided.

The CHAIRMAN stated that that morning he received the following letter from Mr. Gaine, the general manager of the National Telephone Company:—

"Gentlemen,—The attention of the Board of Directors of the National Telephone Company has been called to the meeting of subscribers to the Sheffield Telephone System, convened for the 9th inst., at which it is announced that you will preside, and it has been reported that the proposed new tariff has not met with general approval. On behalf of the Board, I beg, therefore, to put the views of this Company briefly before you. The Board considers that the telephone, as an important aid to business, has passed the experimental stage and become a necessity, and that the proper basis of the telephone tariff is to charge the consumer according to the use made by him of the telephone. This is the principle on which the charges for gas, electric light, &c., have always been made, and the charge for water has practically been arrived at by a somewhat similar means. It does not appear to the Board to be equitable that the subscriber who uses the telephone but three times a day on an average should pay as much as one who uses it 30 times a day. This principle has been recognised in several of the continental exchanges, where telephonic communication has been developed further than in this country; and it is with a view to dealing fairly with the subscribers that the Board put forward the new tariff as an experiment in what they believe is the true direction. If, however, the feeling of the subscribers in Sheffield is opposed to such a system, the Board desire to meet their views so far as they possibly can, having a proper regard to the commercial interest of the Company; and if I may, on behalf of the Board, be permitted to make a suggestion, it would be that a conference should take place between certain representatives of the subscribers and the Company. The Board are confident that consequent upon the amalgamation of the two telephone systems at present at work in Sheffield, they will within a very short time be able to supply a telephone service which will satisfy the subscribers; and the Directors are most anxious to acquire and maintain the subscribers' approbation and goodwill."

The CHAIRMAN said there could be no doubt as to the unanimity of the subscribers in objecting to the proposed tariff. The large attendance was a clear indication that they were not going to have any "fancy work."

Ald. W. H. BRITTAIN (President of the Chamber of Commerce) proposed—"That in the opinion of this meeting the revised tariff of rates which, on April 20, 1892, was submitted by the National Telephone Company, to the Sheffield subscribers, is excessive, and would prove most oppressive to the community of the district; and, further, that the scheme is an ill-considered one, and calls for united action on the part of subscribers." This was practically the same resolution as was passed by the Council of the Sheffield Chamber of Commerce last week. There were 100 gentlemen in that room who were masters of the situation. The proprietors of the rolling mills and tilts had only to decline to subscribe to the National Telephone Company.

Mr. R. COLVER seconded the resolution. There were, he said, something like 1,500 subscribers, and the number of messages sent per annum was 3,615,444, which gave an average of 2,410 for each subscriber. Assuming that each subscriber in future sent his full thousand messages a year, there would be 2,115,644 to be paid for at the rate of a penny each. These would produce £8,815. 3s. 8d. But many of the subscribers would not use the telephone a thousand times a year; whilst others would use it much more extensively; and as all the messages above one thousand would have to be paid for, he estimated that the Company would receive an income from this source alone of more than £11,000 a year. The amount obtained from the fixed charge of £7 a year from each subscriber was £10,500; so that from these two sources the Company would receive an income of £21,815 for an undertaking which he believed had cost them less than £50,000. He was not, he thought, committing a breach of confidence when he said that the proprietors of the whole of the rolling mills would cease to be connected with the Company's telephonic system if they did not withdraw their revised tariff.

Mr. PERCY HOOLE pointed out that the Company must have wires, and must also have posts. If people refused to allow this, the Company would come to grief.

Mr. F. R. BOOTH, the secretary to the Rolling Mills Association, mentioned that the members of that body had decided not to pay the proposed tariff, and, if necessary, to give up the Company's system altogether.

Mr. C. V. BUNTING stated that the Tilters and Forgers' Association had come to a decision similar to the one arrived at by the Rolling Mills Association.

Mr. A. T. WATSON said he had been in communication with the New Telephone Company.

Mr. F. E. SMITH said the subscribers had the whip-hand of the Company in every respect. He considered the town would be better served by the New Company. His opinion was that the Company was not to be trusted, and the sooner the subscribers had done with them the better.

The resolution was then put, and was carried unanimously, and a committee was elected.

The CHAIRMAN then stated that Mr. Gaine was present, and wished to address the meeting.

Mr. GAINE said this was the first time he had had the honour of addressing a Sheffield audience. He would at once and unreservedly say, on behalf of the Directors and himself, that it was their wish and absolute intention to have peace with their subscribers and to meet their wishes. The theory and idea of the Directors of the Company was to popularise the telephone as far as they could. He thought that those who used the telephone in a minor degree ought to pay less. Be that as it might, if it was not the view of subscribers and the people of Sheffield it certainly would not be forced down their throats. He could only add that when the committee just appointed met the Directors of his Company they would find that the Company intended to be reasonable and fair, and would meet the views and the wishes of their subscribers in Sheffield.

The proceedings then terminated.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-NIGHT) FRIDAY, May 13th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "An Instrument for Drawing Parabolas." By R. Inwards, F.R.A.S. (2) "Some Electrical Instruments." By F. H. Nalder. (3) "An Instrument for Measuring Magnetic Fields." By E. Edser and H. Stansfield.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The New Star in Auriga." By Dr. William Huggins, F.R.S.

MONDAY, May 16th.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

8 p.m. Paper to be read: "The Art of Internal Illumination." By W. H. Preece, F.R.S.

TUESDAY, May 17th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Photography in the Colours of Nature." By Frederick E. Ives.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "The Distribution and Measurement of Illumination." By A. P. Trotter, Assoc. M.Inst.C.E. Paper to be read (time permitting): "The Measurement of High Temperatures." By Prof. W. C. Roberts-Austen, F.R.S.

WEDNESDAY, May 18th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "Colour Blindness." By Capt. W. de W. Abney, F.R.S.

THURSDAY, May 19th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Chemistry of Gases." By Prof. Dewar, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting.

The Electrician.

ublished every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co." All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:— Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Phillippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

THE MEASUREMENT OF RAPID PERIODIC EFFECTS.

When it is desired to measure any quickly changing phenomena, like those which occur with alternating currents, ordinary instruments are far too sluggish for direct use. If the quantity to be measured is periodic, so that its value repeats itself after a given interval, it is always possible by means of a contact apparatus, making an instantaneous connection once during every period, to obtain a steady deflection with ordinary instruments. The quantity can thus be found at any particular instant, and by means of several experiments a curve can ultimately be obtained, showing the way in which it varies with the time. This method has been used in several valuable investigations on alternate currents, but it is not altogether satisfactory, as it takes a considerable time to make all the measurements needed. Another method which has been much resorted to for various purposes is that of instantaneous photography on a rapidly moving sensitised plate. This method is applicable whether the phenomenon under investigation is periodic or otherwise, but it requires special knowledge and skill. It has been used with much success in some beautiful researches by Lord RAYLEIGH and Prof. C. V. BOYS on the various forms assumed by the liquid particles in jets of water; and it was also resorted to by M. BLONDEL in some valuable work on the variations of current and voltage occurring in an alternating-current arc.

A more ambitious method than either of these is sometimes applicable when the phenomenon to be tested is periodic. It consists in making a spot of light trace out on a screen the actual curve which it is desired to find. The process

Digitized by Google

is always some modification of the beautiful method first used by LISSAJOUS for studying the vibrations of tuning forks; and which has until lately been but rarely used outside physical laboratories. Some important applications of it are, however, now being made. The principle of the method is that a ray of light is reflected twice, in directions at right angles to one another and to the original path of the ray, by two rapidly moving mirrors, the motions of which are controlled by the values of the two quantities it is desired to compare. The ray so reflected is received upon a screen, and traces out a curve which gives the relation required. It will be remembered that, in a communication made some months back to the Physical Society, Professor PERRY described a new steam engine indicator, the working of which depended on this principle. By an ingenious contrivance one of the mirrors was dispensed with, the single mirror being subjected to two motions at right angles, the first being caused by the pressure of the steam, and the other by the motion of the piston. Dr. FRÖLICH about the same time described an important method for analysing alternate current curves. This also was an example of LISSAJOUS' method. One of the reflecting mirrors was rotated by the armature of the alternator, and the other was attached to the vibrating diaphragm of a telephone traversed by the alternating current under test. This apparatus aroused much interest at the Frankfort Exhibition, where it was exhibited by Messrs. SIEMENS and HALSKE.

Again in the April number of the *Philosophical Magazine* Mr. JOHN TROWBRIDGE describes an instrument which he calls a phasemeter, and which appears likely to prove useful in connection with the study of alternating currents. The method is merely that of LISSAJOUS, with two telephones replacing the tuning forks. Mirrors are attached to the diaphragms of the telephones, the axes of which are so placed that a ray of light reflected from both mirrors receives two deflections at right angles. The instrument lends itself very readily to the demonstration of the difference of phase which exists between the currents in branched circuits, and to the influence of different kinds of iron and steel in increasing the impedance of solenoids. The immediate object of Mr. TROWBRIDGE'S experiments was to seek evidence of wave propagation in the magnetism produced in a lengthy magnetic circuit by two magnetising coils traversed by alternating currents. Two test coils were used in connection with the telephones to investigate the magnetism in different parts of the circuit, and distinct evidence was obtained of differences in phase, though none was found of wave propagation. Further experiments were made which may be regarded as a practical demonstration of the truth of the results recently published in these columns by Profs. THOMSON and EWING, for by experimenting with a test coil imbedded in the interior of the core it was proved that the lines of force concentrated themselves at the surface of the iron. As the eddy currents produced in a solid core subjected to alternating magnetic force necessarily lag a quarter of a period behind the magnetism producing them, it might have been expected that the density of the lines in the inner part of the core would differ in phase from its value at the surface. An effect of this kind was looked for, but was not apparent, and this is the more remarkable as the iron core was no less than half an inch thick, and the eddy currents must, therefore, have been of considerable magnitude. Mr. TROWBRIDGE'S instrument may prove serviceable in studying the manner in which lines of force reverse under the influence of alternating currents. This is a subject about which as yet very little is known, and which is worthy of careful investigation.

REVIEWS.

Diaries of Sir Daniel Gooch, Bart. With an Introductory Notice by Sir THEODORE MARTIN, K.C.B. (London: Kegan Paul, Trench, Trübner, and Co.)

The late Sir Daniel Gooch was a striking instance of the attainment of honour, wealth, and power by one of humble origin. In his case it is the old story of thoroughness and devotion to the interest of his employers leading to success, or, as he himself puts it, "a determination not to be led into changes by the inducement of immediate advancement." Born at Bedlington, Northumberland, on August 24th, 1816, after a mischievous boyhood, during which, however, he secured a fair education, he entered the moulding department of the Tredegar Ironworks, afterwards passing into the pattern-makers' shop. In 1834 he began work at the Vulcan Foundry, near Warrington, under Mr. Robert Stephenson, the works being chiefly intended for building locomotives. In 1835 he went to the Dundee Foundry as draughtsman, and both while there and at Tredegar made experiments with the object of using the galvanic battery to generate power instead of steam. A year later young Gooch entered Mr. R. Stephenson's works at Newcastle, where he became impressed with the importance of the wider gauge, as a champion of which in later life he took a leading part in the Battle of the Gauges. In 1837 he went to Rochdale, and worked on the Manchester and Leeds Railway. In the same year Mr. Brunel appointed him in his 21st year locomotive engineer to the Great Western Railway, which post he held until 1864. About this time Mr. Gooch took a great interest in the "Great Western" steamship, which was built from Mr. Brunel's designs, and proved to be a successful ship, notwithstanding that Dr. Lardner *proved* she could not cross the Atlantic. At this time he designed two classes of engines for the Great Western Railway, which at the end of 28 years continued to do their work admirably, running at 60 miles per hour with good loads. In 1840 he took out a patent for steeling the surface of rails and tyres, but found so much trouble connected with it and the false position in which he was placed toward the Company that he never took out another patent, and further held a strong opinion as to Patent Law, which he looked upon as a curse to the country, and one which could not be worked with perfect honesty. "Patents are taken out for all kinds of absurd things by people with little or no practical knowledge of the work they undertake, and the really practical man in carrying out his work is met at all points by the claims of some patentee. The absence of a Patent Law would not retard invention. . . . the honour of being the originator of a real improvement would be sufficient stimulus." It is, however, not easy to see that this view would work satisfactorily, especially in the case of inventions upon which large sums have to be spent to bring them to perfection.

In 1843 the "Great Britain" steamship, built by Brunel, was launched. In 1858 the "Great Eastern" was launched, and in 1860 Mr. Gooch became a Director of the Company to which she belonged. In 1862 he was engaged in designing and building engines for the Metropolitan Railway. In 1864 another attempt was made to lay an Atlantic cable, and the Telegraph Construction and Maintenance Company was formed for the purchase of the works of Glass and Elliot and the Gutta Percha Company. Mr. Gooch became a director, and with Mr. (now Lord) Brassey, and Mr. Barber, purchased the "Great Eastern" from the bondholders, who had taken possession, for £25,000. The big ship was chartered for the purpose of laying the Atlantic cable, with which she sailed in July, 1865. The story of the failure of this expedition to complete the work is well known, as is also the successful laying of the 1866 cable, and the repair afterwards of that of 1865. While on the former expedition Mr. Gooch was elected M.P. for Cricklade, and on the accomplishment of trans-Atlantic telegraphy was created a baronet.

In 1869 the French Atlantic cable was laid under Sir Daniel Gooch's supervision, and later in the year the "Great Eastern" started to lay the Suez-Bombay cable. In 1872 Sir Daniel records that the "Great Western" shares had risen to 118, having been at 90 when he became chairman. After laying additional Atlantic cables in 1873 and 1874, the "Great

Digitized by Google

Eastern" was dismantled and finally sold to be broken up. So that the greater part of Sir D. Gooch's honourable career was connected with the "Great Eastern" steamship and the Great Western Railway. After many weeks of suffering patiently borne, Sir Daniel died at Clewer on October 15, 1889.

The "Diaries" are very interesting reading, being written in a natural style, and dealing with many matters of general interest.

The Year Book of Science. Edited for 1891 by Prof. T. G. Bonney, D.Sc., L.L.D., F.R.S. (London: Cassell and Co.).

The voice of the scientist has long been heard in the land proclaiming, by no means *sotto voce*, that life is too short, and the working powers of the majority of men too limited to permit of them keeping pace with the ever-increasing flood of printed scientific matter, for we cannot call it literature, which has resulted, as might have been foreseen, from the spread of science and its consequent *vulgarisation*. "The Year Book of Science," we are told, "aims at alleviating to some extent this difficulty, by presenting a conspectus of the progress which has been annually made, divested, as far as may be, of technicalities. . . . The endeavour of its projectors and compilers has been to select those memoirs in each several department which appeared to be of somewhat exceptional interest, either by throwing light on special difficulties, or by being suggestive of further advances. . . . In this first attempt it has been thought better to err on the side of limitation."

The present volume, which numbers some five hundred pages, is divided into five parts, devoted respectively to Physics, Chemistry, Geology and Mineralogy, Biology (Animal) and Biology (Botanical), the various branches of these sciences being each in charge of one or more specialists. Dr. H. H. Hoffert is responsible for "Electricity," and Mr. P. L. Gray for "Magnetism." The forty odd pages occupied by the electrical events of 1891, in spite of several omissions, form a tolerably satisfactory survey of that period. The researches of Mr. A. P. Chattock on the phenomena occurring at the beginning of electric discharges from points; Prof. Nichols' investigations on the electric discharge between a ball and a point; Prof. Crookes' Paper on "Electrical Evaporation;" the investigations of M.M. Sarasin, De la Rive, Bjerknes, Blondlot, and others, in connection with Hertzian oscillations; M. Bouty's valuable contributions to our knowledge of the dielectric properties of mica; Prof. Mengarini's painstaking researches on alternate current electrolysis; and the year's work of Prof. J. J. Thomson, Prof. Elihu Thomson, and Nikola Tesla, are all summarised; and, what is of great importance, not only are the original sources of information quoted, but in many cases the names and dates of the most accessible reprints in this country are given as well. On the other hand, it is difficult, except on the ground of mere oversight, to understand why no reference has been made to the so-called "Ferranti Effect," the scientific aspect of which was so admirably set forth in the Paper which Dr. Fleming read last May before the Institution of Electrical Engineers, or to the great addition to the chemistry of the storage cell which is to be found in the Paper read before the Royal Society in June last by Prof. Armstrong and Mr. Robertson. Prof. Pickering's theory of dissociation into ions, Prof. Minchin's work on "photo-electricity," M. A. E. Kennelly's investigation into the relative effect of electro-magnetic and electrostatic induction on telephone circuits, and M. Mercadier's researches on the telephonic reproduction of speech, would also appear to be well within the scope of the volume.

The section on "Magnetism," although extremely brief, contains references to all the more important work of the past year, including that of Prof. Ewing, together with Mr. A. Hooper's remarkable experimental confirmation of Prof. Ewing's views; M. Decharme's Paper on "Superposed Longitudinal and Transverse Magnetisation," and M. Bachmetjew's interesting note on the "Influence of Magnetisation on the Thermo-electric Properties of Iron and Nickel."

As a first attempt "The Year Book of Science" for 1891 must be deemed a fair success, but many improvements and alterations will have to be made if its compilers propose that it should become a standard and reliable work of reference. The annual record of each science should, we think, be kept separate. Anyone who required a survey of the complete field could then purchase the entire set of volumes, while those who were only interested in one particular department would not be under the necessity of buying much which they did not want. In reality a scheme of this kind should be carried out on the co-operative principle and in a manner such that its scope is not "cabined, cribbed, confined" by financial considerations. The codification of science is not less necessary than the codification of the law, and if competent men with ample leisure could be found willing to undertake the humble but useful task of collecting, collating, and editing down the voluminous lucubrations of investigators, all over the world, we might hope to see the first fruits of the scientific labours of future generations made easily accessible, instead of, as at present, slowly but surely buried beneath a cataract of ink. If some such work could be brought into existence we might hope that careful abtracts of articles and Papers would be made for it, as a matter of course, by the authors themselves, much in the same way as publishers contribute a copy of every book they issue to the library of the British Museum. Gratitude has been defined as a lively sense of favours to come; in that acceptation of the word we ought perhaps to be grateful for "The Year Book of Science."

L'Année Electrique. By Ph. Delahaye (Huitième Année). (Paris: Baudry et Cie.).

This volume consists solely of excerpts from the French technical journals, and in consequence considerable prominence is given to primary batteries, arc lamps, electro-medical apparatus, and complicated telegraphic and telephonic devices. The extracts are in many cases taken entire, and little or no attempt has been made to present matters in a new light, or to apportion the space occupied by an article to the intrinsic importance of the subject it may happen to deal with. On the other hand, the contents of the book are conveniently grouped together under appropriate headings, and it will no doubt be of value to those who find it necessary to keep by them a sort of potted edition of the French electrical press.

Laxton's Price Book, 1892. (London: Kelly and Co.).

Like all modern books of reference, this well-known publication continues to steadily increase in bulk. The section devoted to electric lighting, although nearly doubled in length since last year, is still too scanty, even if we make allowance for the fact that the electrical industry, compared with carpentry, masonry, ironmongery, and gasfitting, is a very new one indeed. The eighteen pages allotted to electric lighting form but little more than three per cent. of the whole work, and nearly half of this space is taken up with the "Sun" Fire Office Rules, and with definitions of electrical terms. Instead of quoting the prices of two or three firms, to the exclusion of those of other houses, we would suggest that in future editions the electrical section would be more useful as a rough guide to the cost of electric lighting if a special *average* price list for each of the leading prices of apparatus were compiled from the price-lists of the leading makers.

On page 290 there is a rather startling printer's error, which results in our being told that the resistance of copper increases 21 per cent. for every degree Fahrenheit rise of temperature, instead of ·21 per cent. Again, among the "many eminent firms devoting great attention to producing the most efficient well-governed steam engine for electric lighting," an electrical engineer would certainly expect to see the name of Willans and Robinson.

To a regular electric light contractor or consulting electrical engineer the electrical section of this publication is not, in its present state, likely to be of much assistance, although no doubt to one not in the trade it would afford some clue as to cost.

"A Guide to Electric Lighting." By S. R. Bottone. (London Whittaker and Co.)

This is a cheap and concise addition to the long list of books brewed for consumption by amateurs and those extraordinary householders, who, because they propose to adopt electric lighting, are supposed to think it incumbent upon them to "read up all about it." The information given by the author is sufficiently accurate, lucid, and suitable for the purpose

Digitized by Google

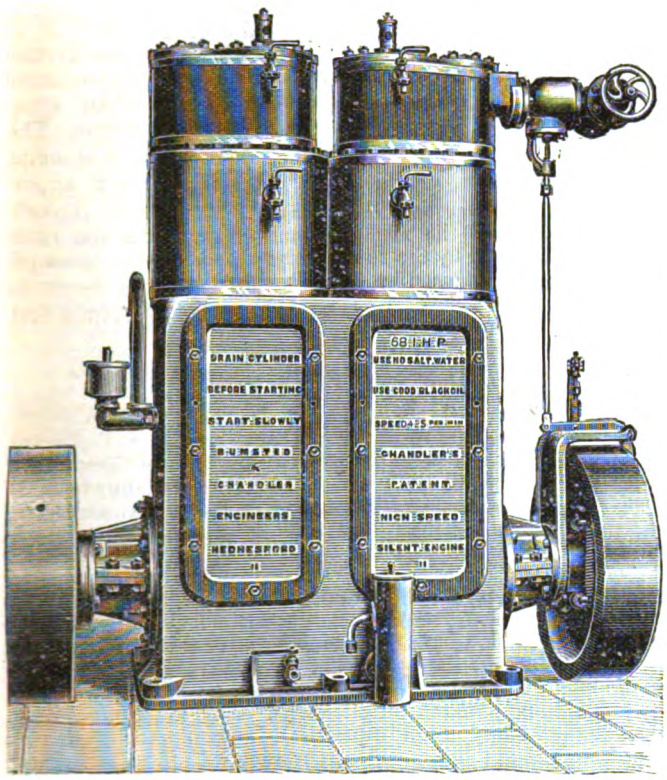
intended. We must, however, protest against the collection of arc lamps which has been gathered together in Chapter III.; it is too archaic, even for a book written for those who know nothing of the subject.

Problémes d'Electricité Pratique. By Dr. Filippo Cintolesi. Traduits de l'Italien par Felix Leconte. (Gand: Librairie Générale de Ad. Hoste).

This is a handy little collection of arithmetical exercises in electrical problems, such as are commonly set in schools and colleges; and although many of them are of "the natural-loadstone rubbed-amber" order, a practical turn is given to a large number.

BUMSTED AND CHANDLER'S HIGH-SPEED ENGINE.

The problem of building a really high-speed silent steam-engine has been solved by very few makers. Amongst the successful ones, the Chandler engine has held a place for many years; and we give herewith an illustration which, while it, unfortunately, gives hardly any information whatever about the engine, is at all events not more uninteresting than those



of other closed motors. The indicated horse-power of this engine is 68, the brake horse-power 61, and the speed 425 revolutions per minute. The diameter of the high-pressure cylinder is 8in., and of the low-pressure cylinder 11in. Both pistons are single acting, and have a stroke of 7in. The point of cut-off in the high-pressure cylinder is at half-stroke. Steam chest pressure is 120lb. Piston slide valves are used, and these can be taken out at the top of the cylinder by removing a small cover. The arrangements for cushioning are such that at 425 revolutions per minute the engine is absolutely silent when exhausting to a condenser. This is owing to a valve which causes a vacuum to act on the under side of the low-pressure piston only, thus the vacuum does not affect the compression or cushion.

Patent Statistics for France.—During 1891 the number of patents taken out in France amounted to 8,079, of which 90 related to telegraphic and telephonic apparatus, 199 to the generation of electricity, and 170 to the application of electricity.

THE PYKE AND HARRIS ALTERNATE-CURRENT DYNAMO.

This alternator is designed to work on the inductor principle, due primarily to Faraday. It embodies the following advantages:—The machine is remarkably solid, and for the space occupied is very powerful. The whole machine consists of two castings, iron stampings, and coils, cheap and simple to construct. Like all machines worked on the inductor principle, it has the advantage of no rotating wire or sliding electric contacts; both the field and armature coils being stationary. A further advantage in the Pyke and Harris alternator is, that in case of the failure of a coil there is a fuse arrangement attached to each connection, which melts before the current from the active coils passes into the defective one.

Fig. 1 is a vertical section, B representing the casting forming an annular space for the inducing coil, and enclosing the latter on three sides. D is the magnetising coil, which is surrounded with an iron casting on its inner and outer circumference, and on one face this casting extends beyond the edge of the coil. The gap is then closed, except at a narrow zone sufficient for the rotation of the inductors, by flat annular soft charcoal iron stampings, arranged so as to form a continuation of the field magnet, and provided with the necessary polar projections. The stampings are rigidly fixed to one another and to the field magnet. Fig. 2 (page 38) is an end view, the right half being shown with the inductors, and the left half without the inductors. The left half shows also some of the polar projections without the secondary coils.

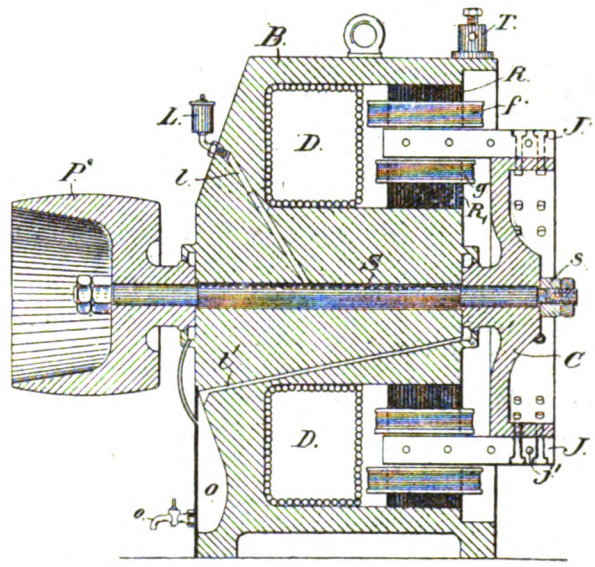


Fig. 1.—Pyke and Harris Inductor Alternator. Vertical Section.

The driving shaft S (Fig. 1) is supported by the casting, and carries at one end the inductors, which are bolted to the gunmetal disc C, while at the other end is fixed the driving pulley P. The shaft is lubricated by means of a longitudinal groove, which is supplied from a lubricator L through an oblique passage *l*.

The inductors are of approximately equal breadth to the distance from centre to centre of contiguous pole pieces. These inductors are subject to great magnetic strains, to resist which requires extreme rigidity. The material of which the inductors are composed requires to be built of the softest iron stampings, which are fixed by bolts of considerable thickness with strong metal supports. One important point in Messrs. Pyke and Harris's machine consists in the use of strengthening plates of steel between the stampings of soft iron which constitute the inductors. In the present machine the inductors are placed parallel to the axis of rotation of the carrier. The plates are separated from each other by thin sheets of paper, as is usual.

Electric currents are produced by revolving the magnetic inductors in proximity to the magnet, which is provided at

Digitized by Google

both poles with polar projections, serving as cores for the conductors in which the current is to be induced. The object of the inductors is to complete the magnetic circuit alternately through each set of polar projections. An even number of polar projections are employed, and the revolving inductors are arranged so that in proportion as one pole is being demagnetised the magnetism of the other poles increases, and *vice versâ*, thus the total magnetic effect being always approximately constant. The induced-current conductor is so arranged that the polar projections which are being magnetised and those which are being demagnetised have a similar inducing action upon it, the magnetising of one set of polar projections thus increasing the effect produced on the same wire by the demagnetisation of the other set of polar projections. This invention may be used in machines for the production of single phase or multi-phase alternating currents or of continuous currents; the polar projections and the induced-current conductor being readily arranged for any desired disposition in the case of inductor machines, with the induced-current conductor placed on the polar projections.

The alternator shown at the *conversazione* of the Royal Society weighed about 7 cwt.; it was 15in. wide, 20in. long, and 21in. high over all. The output was 10,000 watts, and the magnetising current for full load 6 amperes at 50 volts. The clearance allowed between the inductors and the teeth of the stampings was $\frac{1}{16}$in. The casting was of mitis metal, guaranteed 60 per cent. permeability of wrought iron.

THE ST. JAMES AND PALL MALL COMPANY'S MAINS.

The following is a copy of a report presented to the Board of Trade by Major Cardew, R.E., on the subject of some defects which recently showed themselves on the mains of the St. James and Pall Mall Company:—

My attention was called to this damage,* and to two very similar cases of damage to water pipes, by Mr. Wilkins, clerk to the St. James's Vestry, on March 14th. It appeared that a lead water-pipe supplying the premises of Mr. Barker, pastry-cook, &c., whose shop is closely adjacent to that of Mr. Peat, had been eaten through twice within a few months. I examined a piece of pipe which had been thus damaged, and the appearance was suggestive of electric action. Mr. Barker's employés also averred that they had sustained electric shocks from touching the handle of a water tap on a boiler in metallic connection with the lead pipe. As the possibility of electric shocks was a very serious matter, I lost no time in having the main of the London Electric Supply Corporation exposed. This main terminates in a "dead end" nearly opposite Mr. Barker's shop, and I thought it possible that there might be serious leakage from this. But it turned out to be in very good order, and no shock whatever could be obtained from the outer casing of the main. The action on the water pipes, also, was much more likely to be occasioned by a main supplying continuous current. On March 29th I examined the gas meter on the invitation of the chief inspector, and its appearance was thoroughly in accordance with the theory of galvanic or electrolytic action as the cause of the damage. Two holes had been eaten through the back of the meter where it had been in contact with a damp wall, the rest of the meter showing no signs of corrosion. On March 30th I received an intimation from Mr. Wilkins that Mr. Barker's water service pipe had again failed. The ground was opened to remove the defective pipe, exposing a portion of the culvert of the St. James and Pall Mall Electric Light Company, which was laid just above the water pipe; and by means of a few tests with a galvanometer I satisfied myself that there was a steady difference of potential of about 6 volts between the iron culvert and the water pipe, the culvert being negatively charged as regards the pipe. This appeared to me sufficient to account for the mischief, and I notified the chief engineer of the St. James and Pall Mall Electric Light Company of the results of my test, and requested him to give me notice when the culvert was opened, in order that I might be present. Accordingly, I was informed that this would be done on the morning of April 5th. On account of some very important experiments with the new standard ampere balance, I was unable to inspect the culvert until the afternoon, by which time it had been partially opened. There was a good deal of water in it, and in some places this had evidently touched the positive main. There were also three lead-covered wires, which had been used as "pilot wires," lying loosely at the bottom of the culvert. Two of these wires had been fused, evidently by a considerable current, and a good deal of the insulation burned, as was evidenced by a sooty deposit on the main conductors and the culvert at the spot. This had occurred at two separate places, one being near Mr. Barker's shop and the other opposite Mr. Peat's. I have little doubt that a connection between the negative conductor and the iron of the culvert was effected by the fused and stripped ends of these pilot wires. This is confirmed by the following facts:—At the time of my inquiry last November into the explosions which occurred on this Company's system of mains, I found that the insulation of the negative side of their system of mains from earth was very defective. This fault was very persistent, but until the culvert was opened on April 5th it had not been localised and removed. Immediately, however, that this section of the main was disconnected to enable the culvert to be opened, the fault on the system disappeared, and the potential of the positive main from earth, which had been persistently about 190 volts, fell to about 110 volts. The explanation of the action is, I consider, this:—The negative main has been for some months in metallic connection with the culvert in one, or, perhaps, two places in this part of Piccadilly. If the insulation of the positive side had been perfect no electric action would have resulted. But this was not, and, in fact, could not be, the case. Consequently a leakage current was continually passing to earth from the negative at this place, and an equal current in the aggregate from the positive side through many small leaks. The lines of flow of current would be to absolute earth or zero potential in all directions. Any water pipes or gas pipes in the vicinity would be practically at zero potential throughout on account of their metallic connection with the whole mass of the water or gas mains of London. Consequently the lines of flow of current would, to a large extent, converge on any such pipes in the immediate vicinity, if only separated from the charged conduit by damp earth. In other words, there would, necessarily, be a flow of positive electricity from such pipes to the surrounding earth, and thence to the charged culvert. But the flow of positive electricity from a metal into a damp medium, or water, is always necessarily accompanied by the generation of oxygen at the surface of the metal—which, if oxidisable, is thereby corroded. This is the action which has destroyed the water pipes. The gas pipe happened to be laid in bitumen, and was thereby protected, but the gas meter, touching a damp wall within the influence of the leakage, was affected.

The state of the system of the St. James and Pall Mall Electric Supply Company, so far as it has been brought to my notice, may be briefly summed up as follows:—In September last two explosions occurred, due to accumulations of gas and water respectively, a faulty pilot wire causing the explosion of gas. On November 3rd I held an inquiry into these explosions, and, from information given me by the engineer to the Company, I proposed a test, which was carried out shortly afterwards, and revealed the existence of a very serious earth connection on the negative main. This earth connection the Company were unable to localise and remove, and it continued in existence until April 5th, when it was removed by disconnecting the section of main opposite Mr. Peat's, in Piccadilly. The local effect of this fault has been the damages

* Injury to a meter belonging to the Gas Light and Coke Company.

Digitized by Google

now reported on; but it is certain that an equivalent oxidation of metal must have occurred on the positive main, or the house wires and apparatus connected with it, and it is not yet proved that this destruction has been so distributed as not to amount to material damage at any one point. On examination, it is again discovered that the fault originated in the pilot wires. In my report of inquiry I recommended that the Company should at once remove all pilot wires from the interior of their conduits. The Company stated, in answer to this, that they would, as far as possible, be removed; but that they found the wires had, in many cases, adhered firmly to the bottom of the culvert, and could, with difficulty, be removed. These wires, however, in the portion of culvert which was opened on April 5th, did not appear to be adherent to the culvert in any part.

The steps to be taken by the Board of Trade to provide against the recurrence of similar faults and their consequences will, I think, require very mature consideration; but I have no hesitation in recommending that the Company should, without further delay, remove every portion of the pilot wires from the culverts, and should test throughout their system of culverts for the existence of any appreciable difference of potential between the iron culverts and the gas and water pipes.

THE ELECTRIC RAILWAY SCHEMES IN PARLIAMENT.

JOINT COMMITTEE OF LORDS AND COMMONS.

The Joint Committee of the two Houses of Parliament appointed to consider the Bills concerning electric and cable railway schemes for the metropolis met for the first time on Monday, May 9th. The members of the Committee are Mr. Stansfeld (Chairman), the Earl of Lauderdale, the Earl of Strafford, Viscount Barrington, Mr. J. S. Gathorne-Hardy, Mr. Whitmore, Lord Kelvin, Mr. Story-Maskelyne, and Mr. T. H. Bolton; and all were present except the last-named three. The Committee had been instructed to "consider the best method of dealing with the electric and cable railway schemes proposed to be sanctioned within the limits of the metropolis by Bills introduced, or to be introduced, in the present Session, and to report their opinion as to whether underground railways worked by electricity or cable traction are calculated to afford sufficient accommodation for the present and probable future traffic; as to whether any and which of the schemes propose satisfactory lines of route; as to the terms and conditions under which the subsoil should be appropriated; whether any, and, if any, what schemes should not be proceeded with during the present Session."

Mr. G. P. GOLDNEY, City Remembrancer, said, in answer to Mr. WHITMORE, that his attention had been called to the six electric and cable Railway Bills now before Parliament. Only four of them directly affected the City of London. First, there was the Central London Railway Bill. That was a modification of a scheme passed by Parliament last year. It was an electric railway, starting at Shepherd's Bush, and proceeding under the Uxbridge road, Oxford-street, Holborn, and Cheapside. According to last year's Act, it was to end at Cornhill; but the present Bill was to authorise a slight diversion between the Bank and the Mansion House, from whence the line would turn to the north-east, and go on to Liverpool-street, the terminus of the Great Eastern Railway, with which, however, it was not proposed to effect a physical junction. The next Bill in point of importance was the Waterloo and City Railway Bill, which proposed to make a line, speaking roughly, from the open space between the Mansion House and the Bank, along Queen Victoria-street, and under the Thames to the west of Blackfriars Bridge, and then by a curve to Waterloo Station. The City and South London Railway Bill was for the extension to Islington of the already working line from the Monument to Stockwell. Then there was the Great Northern and City Railway Bill, which authorised a line to be worked by electricity, but otherwise of a different character from the others, inasmuch as it was to have such a large bore or tunnel as to admit the ordinary railway rolling stock of the country. The other lines would be of the ordinary standard gauge, but would not have their tubes large enough to admit the locomotives and carriages ordinarily in use on English railways. There were two other schemes—the Hampstead and Charing Cross and the Baker-street and Waterloo—but as they did not affect the City he had not given them special attention. As to the four lines he had specially mentioned, the Central London proposed to have a large new station by the Mansion House and another at Liverpool-street; the Waterloo and City line would have its terminus near the Mansion House; and the City and South London Extension to Islington would have a station near London Bridge and one in Moorgate-street, within the City. He had watched generally the working of the South London line, and found that it was carrying an increasing number of passengers. The Corporation Committee had very carefully considered the routes of the proposed railways, and had had reports from their engineers on the subject; and, generally speaking, they considered the routes convenient. If the electric railways were to be treated simply as affording omnibus accommodation, the Waterloo and City Railway was certainly well adapted for the purpose, and the same might be said of the other lines. He would prefer as to engineering details that the Committee should hear the engineers themselves. It was desirable that no portion of the tunnels should be less than 10ft. below the undisturbed surface of the London clay. The Corporation Committee also thought it undesirable that any portion of the public way should be appropriated without some corresponding advantages being given to the public.

Mr. WHITMORE: What do you mean by advantages to the public?

WITNESS: The placing of stations conveniently for the public, the provision of proper accommodation, &c. Of course, in the City every inch of public way is so valuable that we do not want to give it up unless we get a *quid pro quo* in some way. Another point to which attention has been directed is the question of the liability of the companies for injury caused to property by the construction or maintenance of electric or other railways under the authority of Act of Parliament. There appears to be some doubt as to the state of the law. Some of the engineers, I know, are strongly of opinion there will be no vibration to affect the house property near their works; but the owners are afraid that there will be, and they are naturally anxious as to whether, in that case, they will be entitled to recover damages.

Lord THRING: It has been decided the other way, has it not?

WITNESS: Not absolutely, I think. A point of great importance to us, upon which we have had a long report from our engineer, is the proposed large railway station between the Mansion House, the Bank, and the Royal Exchange. That is included in the Central London Railway scheme. Their suggestion is that the whole of that space should be utilised for a large central station, and also for subways for foot passengers not using the railway, so that people might cross from east to west and south to north under cover, and also have access to the stations below. That is a gigantic scheme, and one well worthy of consideration; but, like other schemes of the sort, it can only be carried out at great expense, and, as far as the public is concerned, at very prolonged inconvenience, as the streets would have to be blocked, and great quantities of material would have to be carted away and brought there.

Mr. WHITMORE: Are there any other lines of route which you think would be very desirable?

WITNESS: No. The question of the best obtainable lines of route depends on a great many circumstances, one of them being the question of cost, as the railway companies can go under the streets much cheaper than under buildings. The routes proposed appear to be fairly good; I see no objection to them.

By Viscount BARRINGTON: I believe the engineering authorities are now satisfied that there is no danger to the foundations of St. Paul's Cathedral.

By Lord THRING: By omnibus traffic I mean generally passenger traffic—passengers without luggage.

Mr. J. H. GREATHEAD, in answer to the CHAIRMAN and other members of the Committee, said: I am joint engineer to all the proposed railways. Electricians will deal in detail with the question whether electricity can deal with the traffic that is likely to arise on any of these lines; but I myself have no doubt as to its power to do so. These lines, excepting the Great Northern and City, are all intended as omnibus lines. They are not intended to form junctions with existing railways or to take through trains from other lines. They form a set of lines dealing with the internal traffic of London.

The CHAIRMAN: Do you express the opinion that electricity would be capable of dealing with the traffic which might be expected to be conveyed on these lines, even supposing the lines were capable of taking up the ordinary rolling stock of the country?

WITNESS: Yes. The Great Northern and City Railway, although it is to be worked by electricity, will take trains through from the main line. On all the other lines except the Hampstead and Charing Cross, the electric power will run trains capable of seating about 336 passengers. These trains can be run, if necessary, every three minutes. I have made a calculation as to the numbers that could be carried on each of the lines. Taking the Waterloo and City line, for example, with a five minutes' service, they could carry 15,500,000 passengers per annum, or with a three minutes' service nearly 26,000,000—that is, assuming each train to be only one-third full. The diameter of the Great Northern and City Railway tubes will be 16ft., whilst the diameter of the tubes on the other lines will be 11½ft., and the outside breadth of each carriage about 9ft.

Viscount BARRINGTON: If there are to be no junctions uniformity of gauge and diameter would not be necessary?

WITNESS: No; but I think it would be desirable to have uniformity where convenient in case it should be required to make junctions in future, but I think it would not be desirable that the lines should be made capable of taking the ordinary existing rolling stock.

By Lord THRING: These railways will be capable of taking passengers' ordinary luggage if necessary.

Lord THRING: It is suggested that you will affect telephone wires and electric lighting wires.

WITNESS: That is a subject which has been carefully considered in connection with an overhead line. The question was referred to Lord Kelvin, who gave his opinion that the telegraph and telephone wires would not be affected. I may add that in connection with the City and South London, which is now working, we have had no complaints as to the telephone lines being interfered with, although there was at one time some slight disturbance in the earth currents, reaching as far as Greenwich and Tottenham. There is no reason why these lines should cause any disturbance of the telephone wires.

Lord THRING: Are you willing to accept a clause to the effect that you shall not be exempted from the common law of nuisance, so that if your generating stations do turn out to be a nuisance you shall not be able to plead the protection of your Act of Parliament?

WITNESS: I am afraid it would be a dangerous thing to accept such a clause, because it would open the way for all sorts of claims upon us; but I should say that any nuisance arising from our generating stations would be nothing at all comparable to that arising from the working of ordinary locomotive trains like those on the surburban lines. People soon get accustomed to the noise, and it ceases to be a nuisance.

Digitized by Google

WITNESS then pointed out in detail the routes, &c., of the various proposed lines, viz., Waterloo to the Mansion House; Baker-street, *viâ* Regent's Park, Portland-place, Oxford-circus, Regent-street, Piccadilly-circus, Haymarket, Charing Cross, and Northumberland-avenue to Waterloo; Hampstead, *viâ* St. Pancras and Tottenham Court-road, to Charing Cross; London Bridge to Islington (extension of existing City and South London Railway); extension of authorised Central London Railway (Shepherd's Bush to Cornhill) to Liverpool-street; and Great Northern and City Railway, from a junction with the Great Northern near Drayton Park, to Finsbury-pavement.

In answer to Lord Thring, WITNESS said there would not be much nuisance caused by the carting of soil. The surface would be opened at the stations, and nowhere else, and the carts would be loaded on the sites of the stations. The quantity of material to be carried away would be very small as compared with what has to be removed in the case of an ordinary railway. The carting of material might cause some slight inconvenience to somebody whilst it was going on, but that would be only temporary; whilst the railway, when it was made, would be there for ever.

Replying to further questions, Mr. GREATHEAD said that if they could pass under buildings at no greater cost than under streets it would be desirable in some cases to do so, as they could thereby improve their curves; but it would not affect the question of gradients, as they were deep enough down to be independent of the surface gradients. As to generating stations on the Central London Railway, the only depôt would be at Shepherd's Bush, adjoining the coal yard of the North London Railway. The only generating station for the Waterloo and Baker-street Railway would be on the south side of Waterloo Station, and there also would probably be the generating station for the Waterloo and City Railway. The generating station of the City and South London Railway will be, as now, at Stockwell, and for the Great Northern and City it will be at the junction with the Great Northern at Drayton Park. The generating station for working the cable railway from Hampstead to Charing Cross will be near Chalk Farm Station. The ventilation on all these lines will be done by the trains themselves, which, being in separate tunnels, will drive the foul air out and draw fresh air in as they enter and leave the various stations. That has been practically tested on the City and South London line.

Mr. BIRCHAM, Parliamentary agent for the promoters, inquired what evidence the Committee proposed to take. He was prepared with such witnesses as Dr. Hopkins, Mr. Preece, Mr. Siemens, and others, as to the motive power to be used, and so on, if the Committee thought it desirable to hear them.

Mr. GATHORNE-HARDY suggested that they hardly wanted evidence as to the sufficiency of electricity as a motive power.

The CHAIRMAN (after consultation with his colleagues): One scientific witness will be sufficient.

The Committee then adjourned till Thursday.

At the meeting of the London County Council on Tuesday last the Parliamentary Committee reported that the Council's Committee proposed to submit to the Joint Committee the following propositions, among others, as indicating the position which the Council would take in the coming inquiry:—"(1) That the size of the tunnels of the lines should be sufficient to allow in the future of an interchange of traffic with existing railway lines; (2) that, subject to the other conditions, and to any geological or other unforeseen difficulties which may be met with, underground lines should not follow the line of existing streets, but should go from point to point, the depth below the surface being such as to avoid injury or inconvenience to buildings in the line of the railway; (3) that the companies should only be allowed to acquire the right of forming the tunnels without acquiring any absolute freehold in the soil, paying compensation for actual damage only." The Committee were of opinion that the traffic capable of being accommodated by a railway of the class proposed between the north and south of London was not of so large an extent as to justify more than one railway.

Mr. SAUNDERS moved as an amendment, "That the suggestion that only one such line should be constructed between north and south London be omitted, and that evidence be placed before the Joint Committee showing the importance of continuing into the country electric and cable lines which may pass under London in order to relieve the congestion of population and encourage building in the suburbs, and that, subject to the above, the course taken of the Parliamentary Committee be approved."

The amendment was agreed to, and the report of the committee as amended adopted

---

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 29, 1892.

The Chicago Exhibition Lighting.—What is undoubtedly the largest lighting contract ever let in this country has brought out very sharply the intentions of the General Electric Company. This Company, as your readers are aware, is made up of the Thomson-Houston and Edison Companies. The contract referred to is that of lighting the grounds and buildings of the World's Columbia Exposition at Chicago. As the matter stands now the contract has been let to the General Electric Company at the rate of $5.95 per light, or a total of $353,000. The first bid of the Company amounted to a total of $1,700,000, the reduced bid being brought about by the opposition of the Westinghouse Company, which put in a bid of $5.49 a lamp. It is said that Mr. Westinghouse still entertains hopes of getting the contract, and that he has offered to furnish bonds for $500,000 to do the work and to make a cash deposit of $50,000 to bind him to do it $50,000 cheaper than the General Electric Company. He is in New York to-day on business connected with this contract. The circulation of the reports concerning this action of the combined companies has brought out considerable unfavourable comment from the daily press. The *New York Herald*, for instance, begins an article in this morning's issue by saying that "it only remains for some enterprising syndicate to obtain control of all the air and water in the United States to put all its citizens completely in the corporate grasp." So much attention has been directed towards the Westinghouse interests by this action of the combination that the Westinghouse stock has almost doubled its value in the last two weeks.

The Allotment of Space in the Electrical Building.—The allotment of space in the Electrical Building in the World's Fair has just been made by Chief Barrett, and is distributed as follows among the foreign countries:—England, 20,000 sq. ft.; France, 16,000; Germany, 20,000; Austria, 1,100; Switzerland, 1,100; Belgium, 1,100; Mexico, 500; Spain, 500; Italy, 500; Russia, 500; Holland, 440; Denmark, 440; Norway, 440; Sweden, 440. The entire electrical building covers 245,000 sq. ft., being 700 × 350ft. The space allotted to the German and English exhibits is in each case 20,000 sq. ft., about 7,000ft. of this space is in each case on the floor. It is said in the German exhibit there will be at least one 1,000 H.P. motor and one 1,500 H.P. generator.

The Edison Filament Case.—The case of the Edison Electric Light Company, *v.* the United States Electric Light Company, well known as the Edison filament case, which was called in the Circuit Court of Appeals in this City last Monday, has continued before the Court through the whole week, and it is said that there is some hope of finishing the argument to-morrow. This is the first case upon the docket of this new Court, and in presenting the case the Court room has almost been turned into an electrical laboratory, and counsel on both sides have gone into the details of the subject so fully that the arguments partook very largely of the character of elementary lectures on electricity. Although the case may be closed this week, it is not likely that the opinion of the Court will be handed in inside of a month.

The Commercial Cable Company.—The annual report of the Commercial Cable Company was filed in the County Clerk's office in this city to-day. On January 1st last the Company had issued $7,716,000 of its authorised capital stock of $10,000,000, and its debts do not exceed $2,000,000, its assets are declared to be at least $10,000,000. The report is signed by John W. Mackay, A. B. Chandler and others, for the Directors. Among the many stockholders may be mentioned Jas. Gordon Bennett, Blake Bros. and Co., Sir Adolphe Caron, K.C., Earl of Leicester, H.R.H. the Duke of Connaught Lieut.-General Sir Peter Lumsden, and Sir Donald Stewart.

The Amalgamation of the Edison and Thomson-Houston Companies.—It is reported that June 1st is the date set for the actual amalgamation of the Thomson-Houston and Edison Companies. At present they are controlled by two individual Boards of Directors and two separate sets of officers; but it is announced that on that date a single set of officers and a new Board of Directors will take charge of the affairs of the Consolidated Company, and that either Mr. Coffin or Mr. Twombley will be the president.

British Association Meeting in Edinburgh.—One of the evening lectures to the British Association at the meeting which is to be held in Edinburgh in August of this year is to be delivered by Prof. J. A. Ewing; and the Saturday evening lecture to artisans will be delivered by Prof. C. Vernon-Boys.

CORRESPONDENCE.

"THE KELVIN."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your to-day's number I see notices and tests of the name "kelvin" proposed for the "Board of Trade unit."

The Board of Trade had kindly wished to adopt this name, and had taken the necessary preliminary steps for introducing it into the Provisional Order for this year. But I have pointed out some reasons why this should not be done; and I am permitted to say that the Provisional Order will not introduce any new name.

I agree wholly with your short leading article on the subject except its first sentence, of which I can only say that I appreciate its kind reference to myself.

It seems to me that the difficulty which has been felt in the cumbrousness of the name "Board of Trade unit" will be obviated wholly and in the most simple manner by using "supply unit" to denote the particular unit defined by the Board of Trade for the reckoning of electric supply. Thus, supply meters, by whomsoever invented, will give their readings in supply units. Ordinary householders, who know nothing of ergs, of meg-ergs, of joules (though knowing the name and something of the work of Joule), of watt-hours (though all know James Watt), will naturally use the simple word "unit" in checking and paying their electric lighting accounts. In scientific statements such as those of page 3 of your to-day's number, in which you test the convenience of "kelvin," the double word "supply unit," with only four more letters, will perfectly distinguish the particular unit intended from all others.

I remain,
Yours faithfully,
6, Cadogan-place, S.W., May 6. KELVIN.

PACIFIC CABLE SCHEMES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Had it not been for the last paragraph of your article on the above enterprise, it is probable that the remaining part might have been left to your discerning readers to judge whether the arguments were weak or strong; but the spirit in which the finishing peroration has been writ is unworthy of the cause. The word "never" might have been used more faithfully than "later," as from the evident point of view of the writer of this article this proposed Pacific connection will never be required; but, Sir, the cry of "wolf" has met with so little success in view of the submergence of many new cables that it may be reasonably supposed that this will be once more ineffective.

I would ask you to allow me briefly to say that, granting the statement that a cable may be cut in time of war, it would occur to a thoughtful statesman that important use might be made of a quick communication before and up to the time of the declaration of war, when future movements up till the last moment might be transmitted, and also the fact of the declaration itself. It would be far better if an island or country were thus able to make everything ship-shape, rather than receive notice by the enemy's cruisers. Then the neutralisation of cables may yet be hoped for.

Following the prominent parts of your article I would say that there is little sentiment nowadays connected with cable schemes, excepting, perhaps, where monopolies still flourish. There cannot be any elsewhere by reason of the dividends which have to be scrambled for.

In the Pacific scheme it may be safely said there are no difficulties which may not be overcome, not even the raising of capital at a reasonable price. There is, however, I should imagine, a route amissing from your chart, by which the coast of Alaska might be cut out if need be, and Unimak need not be connected, although from your article I see no valid reason for missing the place. The great circle route need not be followed out in its entirety, as your dotted line shows, from Vancouver, and another route might be a profitable one; I should think much more so than any you have indicated. The ratio of telegraphing value so ably parodied by you might be received by a neutral with some distrust, as if there is so little value in Cathay why should there be such a race to bind John Chinaman to a rate agreement (vide Shanghai telegram, *Standard*, April 8, 1892)? There must be some considerable amount of traffic, or these many years hitherto unsuccessful wheedling would not have been thought worth the candle.

The English climate is very bad, and fogs sometimes exist on its coast, yet it would take some time to enumerate the number of cables coming to this country. They prevail also on the Atlantic as well as on the Alaskan coasts, about Halifax, N.S., for months at a time, yet there are three cables running into this port. There are four to Newfoundland, on whose banks there are occasional "mists," and, Sir, I have felt in one week's time no less than five severe volcanic shocks; and other places have been wrecked from the same cause, and still the cable messages go on their way rejoicing.

On looking at the map one is also distressed to find there is a cable from Naples to Palermo, which should certainly be taken up, or Vesuvius removed; but I would suggest that eruptions, &c., on shore are an element of safety seawards.

One word about the capital of £2,100,000. I do not think that this large sum would be necessary to connect Vancouver with Australia if the best route be taken, and it may reasonably be supposed that a profit might accrue at something less than the present Australian rate of from 9s. 5d. to 3s. 10d., and to Japan at from 10s. 8d. to 8s. per word.

In conclusion I think, Sir, that the profile you have shown may be left to experts. It would, however, suggest itself to an outsider that it might have been so far "jumped" up that the peaks may have been shown to serve as points for the planting of poles. A small profile is a very dangerous thing, and is not near so "wicked" looking as a greatly elongated one.

I hope you will yet be wishful of the rapid submergence of a connection which has so long been in embryo, and which is so necessary to manufacturing countries, such as Japan (vide *Japan Weekly Mail*) and our own.—Yours, &c., J. R.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I thank you for the opportunity of replying to "J. R." in this issue:—

It stands to reason that the connection most likely to obtain subsidies from the British, French, and the seven Australasian Governments is more likely to be adopted and profitable than "another route" which "might be a profitable one." Your correspondent's comparison of the English and Atlantic meteorological conditions with those of Alaska —"the most foggy and stormy region in the world"— requires no comment. Your critic is unhappy in selecting Vesuvius to poke fun at as a model of virtue. Although it has given itself out as a reformed character since the introduction of Christianity into Italy, it is not by any means guiltless of attempts on the lives of innocent submarine cables. No doubt this Mont de Piété has only been lying low in case "J. R." and his friends should remove it, together with Pompeii and the Colosseum, to the Chicago Exhibition. There is evidence to show that a direct line of subterranean volcanic communication exists between Vesuvius, Stromboli, Volcano, and Etna; and one cable alone, crossing this line, was four times interrupted in less than three years by submarine volcanic action, the ends recovered being charred. Other instances exist of 12 to 60 miles of cable being swallowed up in this way, and a cable across the Straits of Sunda disappeared entirely. Unfortunately for your correspondent, mere *badinage*, however clever, will, no more than sentiment, remove a foggy climate, heave up the bed of the Pacific, obviate submarine earthquakes and landslips, squeeze the continents of the world nearer together, raise money at a low rate of interest, internationalise submarine communication in time of war, cheapen the price of cables, nor increase telegraphic traffic.—Yours, &c.,

THE WRITER OF THE ARTICLE.

ON THE RETARDATION DUE TO IRON PIPES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In answer to the question put me by your correspondent "H. W. W." (*The Electrician*, May 6th, p. 17), the losses referred to in Mr. Preece's recent Paper will not occur with a three-wire alternate-current system of mains when the three wires are enclosed in one pipe. This follows from the fact that the algebraic sum of the currents in the three wires is zero at any section.—Yours, &c., J. A. EWING.

TRANSFORMER PREDETERMINATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the first article by Prof. Fleming on transformers, contained in your issue of April 22nd, there is, I think, a disagreement between equations (13) and (14), p. 655; (13) I think should be

$$\frac{44}{7}\frac{N}{l}I = B = \left(\frac{E\,10^8}{p\,S\,N}\right).$$

—Yours, &c., E. STANLEY SHOULTS.

Rowsley, North Finchley, May 4, 1892.

[Our Correspondent is correct. Equation (13), p. 655, was misprinted and escaped correction in proof.—ED. *E.*]

PHOTOGRAPHS OF RIFLE BULLETS, &c.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the Note which you published in your last number on the bullet photographs which I have exhibited at the Royal Society *soirée* and elsewhere, you stated that the atmospheric phenomena had not before been observed. This is not the case. Mach and Salcher have obtained photographs showing the air waves and the vortices in the trail of the bullet, but their method did not admit of such clear definition, especially in the case of the atmospheric disturbances, as that which I have developed. At the South Kensington Museum and elsewhere I have explained Mach and Salcher's method, and shown some of their results, and in the short description of my exhibit printed in the programme of last Wednesday I referred to their experiments, but I was not able in the short time allowed to me to do more than state that they were the first to successfully take photographs of rifle bullets by means of the electric spark.—Yours, &c.,

C. V. BOYS.

MOLECULAR MOVEMENT IN A CONDUCTOR AND ALTERNATE CURRENTS OF HIGH FREQUENCY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—In the "Note on the Molecular Movement in a Conductor," published in your issue of the 22nd April, Prof. Dolbear says of molecular momentum, "If it be not longitudinal it may be transverse," and then supposes the molecules to be rotated, &c. May I ask, first, Is it necessary that the electric current is a rotation of the molecules? Second, Are there not electrical phenomena which cannot be accounted for if the axis of *movement* of the molecules be supposed to be longitudinal with the conductor?

Take the phenomenon which, of all others, requires molecular movement, viz., decomposition in a voltameter. The handing over of atoms, as first explained by Grotthuss in A.D. 1805, would seem to require, if there be such things as atoms, a continually repeated half rotation of the molecules, this action being each time accomplished by a freshly formed set of molecules throughout; because, after each half rotation the extreme molecules are split up, redistribution takes place, and again there is a half rotation, and so on.

Now, the magnetic field at right angles to the supposed "flow of current" would surely be due to the swing round of the molecules in a definite direction, if it be reasonable to suppose every molecule to possess in itself polarity. Then, if we make such a supposition, the electric currents in the conducting wire would also be due to a swing of molecules, which are all set alike, possessing polarity, being made to swing or oscillate upon an axis at right angles to their polarity, and at right angles to the length of the conductor. If the temperature of a body is due to a vortex motion of its molecules in all conceivable directions, this motion would give a certain polarity to the molecules; if this be a magnetic polarity, then the setting of the molecules all one way would give the magnetic field; the same would be the case if all oscillated one way, *i.e.*, if the axis of each vortex be oscillated. If the above be true, an alternation of current is an alternation of oscillation, and if the frequency of alternation be so increased that the alternations coincide with the oscillations of the axis of vortex motion, then the oscillation will become rotation, and at this point the electric current will be destroyed, for there will be a resultant vortex motion. Then can we, or can we not, suggest the following?

First. Intensity of current is the rate of oscillation of the axis of the vortex of each molecule upon an axis at right angles to the magnetic lines of force, and at right angles to the length of the conductor.

Second. Electric pressure is the force exerted in one swing of the axis of vortex motion of the molecules.—Yours, &c.,

Clapham, April 28, 1892. MORRIS C. TIARKS.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The Gas Supply and Electric Lighting Committee of the Glasgow Corporation invite tenders for providing and erecting a switchboard, connections, &c, at the central station in Waterloo-street, Glasgow. Tenders have to be sent in to Sir J. D. Marwick, Town Clerk, City-chambers, George-square, Glasgow, on or before the 24th inst. Plans, &c, can be had of Prof. A. B. W. Kennedy, 19, Little Queen-street, Westminster, S.W. Further particulars will be found in our advertisement columns.

——— The Corporation of Oldham invite tenders for boilers, engines, dynamos, pipes, &c, for central lighting station. Tenders must be sent in to the Town Clerk not later than Thursday, the 19th inst. Specifications and drawings can be seen on application to Prof. A. B. W. Kennedy, 19, Little Queen-street, London, S.W., or to the Town Clerk, Oldham. Further particulars appear in our advertisement columns.

——— The Great Eastern Railway Company invite tenders for various stores, including telegraph materials, signal and point fittings, &c. Tenders are to be in by the 21st inst.

——— The General Post Office are inviting tenders for telegraph arms of good south of England oak (planed, bored, and chamfered). No time is given for the sending in of tenders, and all particulars may be had of Chas. E. Stuart, Controller of Stores, Telegraph-street, London, E.C.

TENDERS RECEIVED.—The following is a list of the tenders received for an installation of telephones and electric bells at the Hotel Metropole, Dublin:—

	£	s.	d.
Manchester and Liverpool Electric Company, Liverpool	855	0	0
Smeeton and Page, London	625	0	0
G. A. Nusbaum, London	600	0	0
R. S. Blackburn, Helsden Bridge	570	0	0
William Johnson and Co., Sheffield	528	0	0
W. A. Shaw and Co., Stockport	495	0	0
J. B. Saunders, Cardiff	460	0	0
Birmingham Telegraph Factory, Birmingham	449	0	0
Harold Clegg and Co., Manchester	430	0	0
Croggon and Co., London	420	0	0
Goodwin Electrical Company, Dublin	419	0	0
William Curtis and Sons, Dublin	400	0	0
Thomas Barton, Blackburn	373	0	0
Maunsell, Mercier, and Co., Manchester	345	0	0
J. Blackburn, Nottingham	315	0	0
E. L. Berry, Harrison and Co., London	300	0	0
Matthews, Ball, and Co., Leicester	293	0	0
McClellan and Co., London	291	10	0
Electrical Engineering Company of Ireland (Limited), Dublin (accepted)	280	0	0
D. and G. Graham, Glasgow	290	0	0
E. J. Dugdill and Co., Manchester	290	0	0
Gent and Co., Leicester	285	0	0
C. C. McCarthy, Belfast	265	0	0
Hills and Thomson (Limited), Liverpool	258	0	0
Jno. Pearce, Glasgow	249	10	0
Jas. Fletcher and Co., Burnley	235	15	0

TENDERS RECEIVED.—Tenders have been received by the Bermondsey Vestry for laying down the necessary plant and fittings for supplying the electric light to the Town Hall, from Messrs. Joel and Co., at £1,068, and Messrs. Siemens Brothers and Co. (Limited), at £1,560; but the Vestry have as yet taken no action.

——— A special committee of the Chiswick Local Board are considering two tenders received for the electric lighting of the district.

APPOINTMENT VACANT. — The Corporation of Kingston-upon-Hull require a capable out-door foreman for their electric light works, at a salary of £2 a week. Applications, which must be in writing, and addressed to Mr. F. Harman Lewis, Borough Electrical Engineer, will not be received after Monday, 23rd inst. Further particulars appear in our advertisement columns.

SALE BY AUCTION.—Catalogues are now ready of the sale by public auction, by Messrs. Wheatley Kirk, Price, and Goulty, at 39, Queen street, London, E.C., on Tuesday and Wednesday next, 17th and 18th May. The catalogue includes a number of new, or nearly new, Brush and Willans engines, Babcock-Wilcox boilers, dynamos up to 45 units by the best makers, transformers, carbons, arc lamps, switches, instruments, &c., &c., comprising the estate of Nicholson and Jennings, and other owners. Included in the sale also are the patent rights in patents Nos. 17,479 of 1888, 4,703 and 9,917 of 1889, and a half share in No. 19,695 of 1889. The sale rooms are situate close to the Mansion House, and the sale commences each day at ten for eleven o'clock prompt.

DISSOLUTION OF PARTNERSHIP.—The partnership hitherto existing between Mr. J. Booth and Mr. L. Ellson, trading as Booth, Ellson, and Co., at Queen-street, Melbourne, and at Adelaide, has been dissolved by mutual consent as and from February 29th last. The business is being carried on by Mr. Ellson at the same addresses, under the style of Ellson and Co.

MUTUAL TELEPHONE COMPANY (LIMITED).—A resolution, passed at a meeting of this Company on April 8th, was confirmed on May 4th,—"That the Company be wound up, and that Edwin Guthrie, 71, King-street, Manchester, be liquidator." Claims must reach the liquidator by the 31st inst.

LEGAL.—In the High Court, on Saturday last, before Mr. Justice Kekewich, an application was made to restrain Messrs. J. R. Fawkner and H. Rogers, electrical engineers, from sub-letting a portion of the large premises recently taken by them in New Bridge-street, Blackfriars, to "General" Booth. The injunction was granted, with leave to serve notice of motion to-day (Friday).

MESSRS. W. SOUTTER AND SONS.—This firm are issuing some neat hanging designs of electric light fittings. Mr. J. J Smith, their London representative, has removed from 28, Holborn-viaduct, E.C., to 47, Holborn-viaduct, and 49, Farringdon-street, E.C. Mr. Smith also represents Messrs. A. and R. Cochran.

NEW RUSSIAN ELECTRICAL COMPANY.—A company has been formed, with headquarters at Moscow and known as the Société Electrotechnique Franco-Russe, to manufacture there all kinds of electrical machinery, and to undertake the construction of electrical tramways, central stations, telephone systems, &c.

ELECTRIC LIGHTING PROJECT.—Messrs. Siemens and Halske, of Berlin, says *Industries*, have sent in a project for the electric lighting of Warsaw in Poland.

MESSRS. G. E. BELLISS AND CO.—This firm have just issued their first complete catalogue of engines, boilers, machinery, &c. Messrs. Belliss and Co. are large suppliers to the British, Indian, and Colonial Governments, and to the Naval Departments of the chief foreign States. The catalogue contains illustrations of the well-known double-cylinder engine with dynamo of the "Defiance" type, the central-valve engine and dynamo of the "Crescent" type, and a number of others. The catalogue contains 60 large quarto pages, is well printed, neatly arranged, the illustrations throughout being admirable.

COUNTRY HOUSE LIGHTING.—Messrs. Ernest Scott and Mountain (Limited) have secured the contract for lighting Benmore House, the residence of Mr. H. J. Younger. A Priestman oil-engine of 18 B.H.P., with a Tyne shunt-wound dynamo of 12,000 watts, and accumulators capable of maintaining 80 lamps for 10 hours, will be used; the installation consists of from 180 to 200 lamps. Mr. W. A. Bryson, of Glasgow, is the superintending engineer.

ELECTRIC LAUNCHES.—Mr. W. S. Sargeant, of Chiswick, is fitting out for the season a number of electrically propelled launches, which include the "Glowworm" and the "Pilot," which are being built for Mr. Andrew Pears, the "Meteor" for Mr. Arthur Ash, and the "Florentia" for Mr. W. T. Crawshay.

CHICAGO EXHIBITION, 1893.—Notice is given in our advertisement columns that applications for space can only be received up to Saturday, the 21st inst., after which date applications will be filed in case any space should be hereafter available, but will not be included in the allotment.

ELECTRO-HARMONIC SOCIETY.—We have received a copy of this Society's balance-sheet, which, subject to audit, is to be presented at the annual general meeting to-day (Friday), at 28, Victoria-street, Westminster, S.W., at 4:30 p.m. The number of members of the Society is now 316. The accounts show a balance of surplus assets of £113.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C. from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

April 19, 1892.

7,361. W. L. SPENCE and B. DEAKIN. Manchester. Improvements in the distribution of electricity by alternate currents.

7,393. E. C. HESS. London. Improvements in telephone receivers.

7,404. S. H. SHORT. London. Improvements in or relating to electric railways and to dynamo machines and motors.

7,412. Sir C. S. FORBES, Bart. London. An improved battery element.

7,415. M. W. DEWEY. London. Improvements in and relating to electric railways.

April 20, 1892.

7,466. A. SHIELS. Glasgow. Improvements in electrical communication on railway trains.

7,487. W. A. S. BENSON. London. Improvements in electric switches.

7,492. H. OPPENHEIMER. London. Improvements in and connected with electric bells.

7,509. H. H. LAKE. London. Improvements in alternating-current electro-magnetic motors, and methods of operating the same. (W. Stanley, junior, and J. F. Kelly, United States.)

7,515. T. GRIFFITHS. London. Improvements in electric insulating composition.

April 21, 1892.

7,569. P. EVERITT. London. Improvements in apparatus for automatically operating electric lamp switches.

7,570. W. T. SUGG. London. Improvements in insulators for electric installations.

April 22, 1892.

7,629. C. E. MASTERMAN and WOODHOUSE and RAWSON UNITED (LIMITED). London. An electrically propelled canoe.

7,646. H. A. MAVOR, W. A. COULSON, S. MAVOR, and W. B. SAYERS. London. Improvements in electric switches or contact makers.

7,649. J. A. TIMMIS. London. A new or improved electric bell push or pull, &c., automatic indicator.

7,655. G. R. NUNN. Manchester. Improvements in electrical call and indicating apparatus.

April 23, 1892.

7,682. F. PRICE. Bristol. An improvement in electro-motors, applicable also to dynamo-electric machines.

7,690. J. A. KINGDON, London. Improvements in electro-motors.

7,717. W. L. WISE, London. Improvements in electric alarm apparatus, for use in connection with railways and vehicles, or trains travelling thereon. (D. Murquletz, Roumania.)

7,718. W. H. AKESTER, London. Improvements in, or connected with electric arc lamps.

April 26, 1892.

7,833. J. WALKER and J. HAMPSHIRE. Dewsbury. An electrical metronome or time-beater or regulator for musical and other purposes.

7,855. C. E. CHALLIS. London. Electric switches.

7,853. M. BINSWANGER. London. Improvements in the construction and insulation of electrical contact devices and like apparatus.

April 27, 1892.

7,915. A. W. ISENTHAL. London. Improvements in electric switches.

7,915. D. MARR. Manchester. Improvements in telephones.

7,961. G. W. PRICE. London. An improved electric circuit-closer.

April 28, 1892.

8,041. S. D. WILLIAMS. Newport. Improved telegraph codes and apparatus therefor.

8,046. H. C. L. HOLDEN, B. M. DRAKE, and J. M. GORHAM. Erith. Improvements in electrical measuring instruments of the Cardew type.

8,062. G. BRYANT. London. An improved machine for giving electric shocks automatically by the insertion of a coin.

8,064. W. A. G. BIRKIN. London. An improvement connected with thread-coating of electric wires.

April 29, 1892.

8,083. J. O. DALE. Birmingham. A means of electrically heating iron, steel, and other metals in the processes of rolling, drawing pressing, and stamping.

Digitized by Google

8,090. J. W. WIGNALL, W. HIRST, and J. SMITH. Manchester. Improvements in the production and regulation of electric currents for lighting and other purposes and in apparatus connected therewith.

8,115. J. B. MILLAR. Glasgow. Improvements in and relating to posts or standards for carrying electric lights, wires, and the like.

8,119. W. J. WARD, junior. Newcastle-on-Tyne. Automatic make and break switch.

8,127. S. EVERSHED. London Improvements in electric telegraphs.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

5,711. THAME. Electrical seamless tubes, &c.

8,457. SPOKES. Electric arc lamps.

8,811. MENGARINI. Recording electric meters.

8,963. SISLING AND OTHERS. Wiring for electric lighting, &c.

9,227. SIEMENS BROS. AND CO. (Limited) (Siemens and Halske). Telephones.

9,249. ROWAN AND MCWHIRTER. Electro-magnets for holding tools, &c.

9,606. THOMPSON. (Stein). Telephone receivers.

9,628. FITZGERALD. Voltaic batteries.

9,629. FITZGERALD. Voltaic batteries.

9,637. ALABASTER AND GATEHOUSE. Electric cut-out.

9,689. JEANTY. Electric batteries.

9,803. ENGLEDUE. Galvanic batteries.

10,090. GRABAU. Electrolytic production of aluminium.

10,261. PIEPER. Electric motors.

10,612. SIEMENS BROS. AND CO. (Limited) (Siemens and Halske). Electrical transformers.

10,613. SIEMENS BROS. AND CO. (Limited) (Siemens and Halske). Rotary phase currents.

14,752. HEALD. Incandescence lamps.

16,451. THOMPSON. (Espian and another). Electric train signalling.

1892.

2,544. BOULT. (Still). Electrical motors.

3,970. MILLS. (Lundell). Dynamo-electric machines.

3,971. MILLS (Johnson). Electric propulsion of vehicles.

3,996. THOMPSON (Shults). Electric adhesive plaisters.

4,152. HERDMAN. Electro-therapeutic apparatus.

4,416. WESTON, W. H. and G. W. Electric switches.

4,610. PINKHAM. Electric gas lighting burners.

COMPANIES' MEETINGS & REPORTS.

Western and Brazilian Telegraph Company (Limited).

The twenty-third ordinary general meeting of this Company was held at Winchester House, Old Broad-street, yesterday, under the presidency of W. S. Andrews, Esq.

The SECRETARY (Mr. R. M. Cunningham) read the notice calling the meeting and the minutes of the last meeting, which were confirmed by the present meeting, and signed by the Chairman as correct.

The CHAIRMAN: Gentlemen, before proceeding with the ordinary business of the meeting I propose to make a few remarks. You will remember that at the last general meeting a vacancy had occurred at the Board, and that the Directors expressed their intention not to fill that vacancy for the present, giving their reasons for that intention. Subsequently, just before this meeting, we received an official intimation that a gentleman would be proposed for election as a Director. In issuing our report we stated this fact, and we also made pretty much the same remarks that we had already made at the previous general meeting. On behalf of this gentleman a circular was then sent round with proxies proposing his election for this meeting. We considered that circular. We thought that it was a very reasonable one, and we saw no reason why we should deal with the question any further. It seemed to us that we had relegated it pretty much to the shareholders to settle, and that the best course to pursue was to leave it there. Following upon this the proxies came in, and we found that there were a large number of proxies in favour of Mr. Coppen, the gentleman alluded to; but I must tell you that previously to this, when we considered the question whether we should reply to the circular at all, we came to the conclusion, informally, that should a substantial number of shareholders, such as would justify us in electing Mr. Coppen to the Board, support that gentleman, whatever our majority might be, we should elect him—in other words, we wanted to go with our proprietors as we always have done, and to act as reasonable men of business. We knew there were a large number of new shareholders. We thought that perhaps those gentlemen felt that, as they had become shareholders since this Board was elected, they were not in such close touch with the Board as they would like to be, and that this was a measure devised by them to bring them into closer touch with the Directors. As soon as the proxies were handed in we saw that they were far in excess of what we had in our minds fixed for a substantial number of shareholders; and, therefore, without waiting for any analysis of the proxies, we at once intimated to Mr. Ennis, on behalf of Mr. Coppen, and also to Mr. Coppen, that the Directors would propose at this meeting, from the chair, that Mr. Coppen should be elected. I may say that after we came to that conclusion, which we did under the impression that there was a considerable majority in our favour, we were told that that majority had dwindled considerably. It would be impossible to say what the majority is, but I may say that I think if there is a majority it is in favour of the gentleman at the other end of the room. I do not know what the shareholders may think of this, but many of them have probably come here to discuss this matter *pro* and *con.*; and in addressing the shareholders now, therefore, I would remind them that we are surrounded by certain opposition, which is always watchful and on the alert, and that as far as possible on this occasion we should strive not so much to discuss matters *pro* and *con.*—in fact, I would rather that there should be no speechifying at all—but that we should aim rather at unanimity. We should endeavour, as far as possible, to be unanimous on the point of Mr. Coppen's election. The Directors look upon it that they are entrusted with proxies for the general purposes of the Company—not at all to be used in any one direction. They are forwarded to us to use them, we think, for the benefit of the undertaking generally; and under the circumstances, looking at the number of shareholders who are in favour of Mr. Coppen's election, we think it is to the benefit of the Company that that gentleman should go on the Board. I do not know that I need trouble you further with this matter. What I have said seems to be pretty much in accord—if I may judge from the expression of feeling at the meeting—with the views of the shareholders; and, therefore, I will now propose to go on with the ordinary matter of the report and accounts. We shall take the re-election of the two retiring Directors after that matter is dealt with, and then I shall have the pleasure of proposing the appointment of Mr. Coppen. No doubt some gentleman who has been supporting Mr. Coppen will second the motion, but if not we shall be happy to second it from the Board, as well as to propose it. Now, coming to the more immediate business of the day, you will have seen, on the perusal of this report, that, to a certain extent, it is anomalous. There is a fair increase in the traffics; but although the volume of the traffic has grown, the money that it produces has been diminished. For the December half of 1890 our receipts amounted to £103,817, whereas in the past half-year they have been £92,345, or a decrease of £16,472; but the whole thing is explained beyond question when we see that for the half-year ended December, 1890, our loss on exchange was £731, while for the half-year ended December last our loss on exchange was £19,133. Now, that, of course, explains the whole thing; in other words, if the exchange this year had been as favourable as it was in the previous year we should not alone have had an increase in the work done, but an increase also in the money earned, and your position would have been practically the same as last year, and you would have had the same dividend. The difference in the dividend is owing exclusively to the loss on exchange, which is, as you all know, a matter absolutely beyond the control, as far as we can see, of any human being. Financiers themselves seem to differ as to what course should be taken with respect to the question of exchange. The full effect of our working does not end with our loss by exchange. When you do 17 per cent. more work it costs you something to do it. The staff, also, have been sickly abroad, and generally we have had anything but a favourable condition of things throughout the half-year. It is, therefore, very satisfactory to see that the total increase in our working expenses has only been £1,200 in spite of all that, and in spite of the increased work done; and, moreover, £400 of this increase arises from a totally distinct cause, which will not occur again. Analysing the expenses, you will find that the increases in Abstract A amount to £1,756 and the decreases to £831. The largest increase has been in connection with the staff at Brazil—in other words, the money has been spent where it has been earned; and I do not suppose that you would desire to alter that. This increase in the expenses of the staff has been caused by a day and night service, which was established, of course, in order to give the public the utmost accommodation. The line has continued open, in other words, and there has been this continuous service given. There are some small increases in the salaries which are paid in currency, which has not the same purchasing power, and therefore in these cases we have had to pay more. The sum of £406, out of this increase, has been on the land line at Rio and on the tug for repairs. Then, owing to the large number of messages handed in, stationery was required sooner, and we sent out a large supply, amounting to £305. Miscellaneous expenses have also increased £86, and altogether there has been the increase that I have mentioned of £1,756, the decreases aggregating £831. The net increase has therefore been £924. As regards the shipping, the "Norseman's" expenses amounted to £8,154; but although there was an increase of £602 in the cost of her coals there was a net decrease on her working of £249. I must, however, tell you that that is more apparent than real, because as a fact the ship was steaming for 97 days instead of 43, and you cannot work a ship for nearly double the time and do it for less money. The ship was employed in laying loops, and therefore £1,325 of her expenses were charged to reserve; there was thus a net increase on her working of £1,075, and that was for working the ship double the time that she worked in the December half of 1890. The expenses of the "Viking" show a reduction. She was at work 66 days instead of 26 days. We had medical expenses to bear, and we were working double the time with the two ships, and on the whole on the working of the two ships there was a small decrease of £68. Under Abstract C, which you always look at with a certain amount of interest—for it represents the London expenses—there is a small increase of £22, which is not worth explaining. It was caused mainly in the Clearing House accounts. We instituted a Clearing House some time back. We got that with the view of ensuring greater accuracy in the messages. All the messages are by

Digitized by Google

this means compared, and any error is traced. The effect of that in the public mind is very great, for they see that our service is more accurate, and I believe it pays a hundredfold its expenses. There is a separate item of £402, which will not occur again, included in the expenses; that is on account of the arbitration, which is now finally disposed of. The outcome of it all is that there is a total increase of £1,204, including the £400 just named. For that we have done nearly 17 per cent. more work—the exact increase is 16·80 per cent.—we have worked under unfavourable conditions with respect to the public health and consequent difficulties in connection with the staff, as they had to be shifted and arranged, and all contingencies had to be met. With all these difficulties and all this increase of business we have unfortunately got £19,000 less money to deal with; but, as I have said, that has been caused by a matter beyond our control. The result is that we bring down a balance of £53,940. We put £15,000 to reserve and £6,293 to debenture redemption fund, and we recommend a dividend for the half-year at the rate of 4 per cent. per annum, carrying forward £4,486. Going next to a small matter, before I touch upon other subjects, you will remember that we discontinued the publication of the traffic returns. We thought that they were too tempting, for they were at that time enormously high. Unfortunately, they have now again gone down considerably, and we saw that the reason which actuated us in stopping their publication existed no longer; and therefore, as in the abstract, the Directors very much preferred to publish them, the publication was resumed. Now, as regards what you are most anxious to hear about, I expect, the competitions, you know that you have been fully informed with respect to the threatened coming of these competitions—I was going to say—almost *ad nauseam*, because they have had to be referred to at nearly every meeting that we have held. We were told at the last meeting that the French line—the French Company as we call it—had been opened, and that competition so far had not done us—I was going to say—any apparent injury. As far as we can trace the matter, that not altogether unsatisfactory state of things still continues. The French line does not appear to do us any great harm. The Central American Company was stopped during a great part of 1891 on account of the war with Chili, so we had not the competition of that line. It was re-established last September, when the war difficulties were over, and they have got to work again. On May 1 they reduced the rates. My impression is that they did that because they found they were not getting enough of the traffic. We followed that reduction to the Argentine and Uruguay. We cannot yet tell what the effect of that will be upon the homeward and also on the outward traffic. Again, at the last meeting, attention was drawn to another line which was threatened, and which we reported to you at the time. We were told that that cable was under construction, and that it would shortly sail. A shareholder, in fact, thought that it had sailed, but that was not the case then. It has, however, sailed since, and that line will probably be very speedily laid between Brazil, Pernambuco, and Senegambia. At Senegambia it joins up with the Spanish International line, which continues from Senegambia along the African coast, and lands finally on the Continent of Europe. It is quite impossible for us to forecast what the result of the opening of that line will be. We know that up to the present time a certain amount of traffic has gone by it which has been handed to us at St. Vincent, and we have obtained a proportion of the toll; but when the traffic goes all through by their own line we shall not get any share of it. We must, however, do the best we can. It must always be remembered that these cables are single lines, whereas we have duplicated our system, and have prepared for these competitions. The next point is that since we last met we have made a very satisfactory agreement with the Brazilian Submarine Company. Under our old agreement we were bound to duplicate our lines when the traffic actually called for duplication. We discussed the whole question in view of the competing lines which were being carried out, and we arrived at the conclusion that the prudent thing was to duplicate the only bit remaining unduplicated over the busy section at once, without waiting for a glut of messages over the one line existing, if that ever came. Matters were discussed, the outlay was pretty considerable, but in the end we came to an agreement on the point; and the Brazilian Submarine Company, upon the laying of this cable, will begin to pay us a fixed rate of £6,000 per annum for all time. We thought in your interest that that was a wise agreement to enter into, and it was wise also in the interest of the Brazilian Submarine Company for the protection of their very large revenues, and they were enlightened enough to see that. The effect of this, of course, will be what you can see by a glance at the map. It is the bit from Santos to Chuy, but you will observe that the completion of that gives us a duplicated system all the way from this country and Europe to Brazil and the countries I have just named, including the River Plate. The lines are duplicated from end to end, and the effect of that we anticipate will be very favourable. I did hope to-day that we might announce the completion of the laying of that line, but it will not be very long before that work is completed, and then we shall enter into possession of this £6,000 a year. Then, with respect to these new lines, I must tell you that we have applied the duplex arrangement to them, which practically, when you get traffic in both directions simultaneously, gives you the benefit of two lines out of the one line, so that instead of having two cables you will practically have three all the way the instant this is completed. That, of course, is as regards carrying capacity. Altogether, when this cable is completed, we shall have laid and paid for—without increasing the capital of the Company by one penny—2,235 miles of duplicated cable. I do not think that that is altogether a very bad performance. You have all of you taken an important part in that, because without your agreement that these large sums should be put to reserve, and so on, this work could not have been effected; and if any justification were needed it not only justifies the reserve, but shows the necessity of it. Over and above this we have come to another arrangement. As you are aware, the Central American Company secured the land running from Valparaiso in a very circuitous direction to Buenos Ayres, their object being to put prohibitive rates against us, so that we should not get any Chilian traffic, which we had previously got over the neutral line. That would have acted very unfavourably; but all the companies interested—the West Coast of America, which was working with us, the Brazilian Submarine Company, and our own Company—met and made arrangements under which the line, ceasing at present at Buenos Ayres, should be extended over the Chilian coast by a land line. That work is actively proceeding, and it will connect us up not merely with Valparaiso but with the number of ports up to Iquique, which you see marked on the map. We believe that this will have a very good effect. It will enable us to compete, and to compete under very favourable conditions, under the Chilian traffic. At all events, the companies interested in this communication have done their best. They have armed themselves, as they conceive, at every point, and they hoped to be enabled to give a good account of themselves. Of course, under all these circumstances, the reserve has been a very rapidly diminishing quantity. You know the old adage—that you cannot eat your cake and have it too; and in our case the reserve is swallowed up, and as against the reserve you have the duplicated lines—in other words, you have increased by two parts the one part which you had of revenue-earning capacity. You are now in a position, or you will be directly, to do three times the amount of work you formerly did—that is to say, if you could do one thousand last year you will be able to do three thousand when this work is completed; and that, I think, is a very satisfactory substitution for the 2½ per cent. interest which you used to get on the reserve. We must do our best to make up some of the reserve as soon as we can. On the whole the financial position of the Company is not unsatisfactory. You know that we have not issued the £50,000 of debentures that we had power to issue. We have not issued them because we always desired, if we possibly could, to prevent anything coming in between the shareholders. We do not want to put anything before you that is not already there, and we are going to do our best to avoid doing so. Including the £12,700 paid off last January, £35,801 of your debenture debt has been paid off. We have, besides, to the credit of the debenture capital fund £28,435. That is all in the right direction. The whole of it is not available—what you have paid off is not, but the other is an available asset. You also have unexpended capital of a little more than £8,000, besides the £43,912 in unsold securities. We calculate that the new cable will be pretty nearly covered by the assets we have, if it were necessary to apply them all in that direction. The cable was put out to tender, and the Telegraph Construction and Maintenance Company's tender was the lowest, and was therefore accepted, that is the Company which is laying the cable; and we know that it is a very good Company. We said in the report at our last meeting that we had removed the remainder of the old deep-sea cable where it was in the deep sea, which was for 200 to 300 miles. As soon as we had done that we thought we saw our way to a small ship. You are more like an omnibus cable—not a deep-sea cable; and, therefore, we may look upon it that your property is a very sound one, and you cannot have such losses on it as are made in the case of some deep-sea cables. We therefore determined to get a new ship, and we have succeeded in putting on the stocks a ship which is to steam at a very high rate of speed. She is to have good carrying capacity—pretty nearly as much as the "Norseman." She will be a steady, first-class ship, and will only be of 900 tons, instead of 1,368; therefore she will be more rapid and will be worked more handily, and we believe she will show much better results than the ship we have hitherto had. The "Norseman" is a very fine and steady ship, and a first-class vessel for working in deeper water; but we do not now want such a luxury, and we desire to work more economically. We shall have to pay for that ship, and she will cost a great deal of money—about £39,000. That was also by tender, and again the lowest tender was accepted. Our surveyors, of course, advised us that the firm tendering was first-class. We hope to get you these things, if we get satisfactory traffics, without issuing that £50,000 of debentures that I have mentioned; and at all events we shall do our utmost to achieve that object. Our success in the matter will depend very much on the state of trade. If trade and commerce are active and give us plenty of business we shall succeed. Another question which the shareholders take an interest in is the debenture re-organisation. The legal difficulties in connection with that matter have all been surmounted, and we were going into that matter with a view of carrying it out when we received a communication which compelled us to stay our hand. We believe, however, that the time has now come again when we can take the question; but we are told by those who know better than we do that it is not yet the time for proceeding with arrangements of this sort, and that it will be better to wait a bit and see how Brazilian and Argentine securities stand in the market. We have had the French competition for the full six months, and we have had that of the Central American Company for the last three months; and what has been the result? It comes to what I began by telling you—not a decrease in the number of the messages or of the words carried, for we have sent more messages and more words. I warned you, I think, at our last meeting that we did not expect to maintain those very large traffics that we had been having, as they were owing to exceptional causes; but I think we have been proved to be in the right—so far as this—that these new lines do not rush in at once, as was supposed by some, and carry off the very large bulk of our trade, for we have held our own. I think it proves a little more than that. I think it proves that the public does not care about change for the sake of change; and that, on the whole, the public does not appear to be dissatisfied with the work of the Western and Brazilian Company and the companies in connection with it, and to that extent we feel considerably encouraged. At the same time, of course, this new line that is laid to Senegambia will make the fourth line

Digitized by Google

competing for the service of South America; and we cannot, therefore, lead you to expect that we are going to maintain all this traffic, though we shall do our best to do so. We have made large reductions from time to time. The new companies, notwithstanding, have made reductions. Why? Not in the interest of the public, but simply for the purpose of intimating that "Codlin is your friend, not Short." They want to get the traffic from our line, and I am pleased to see that the public is not to be hoodwinked quite so easily as had been anticipated. We cannot be behind. Where any reductions are made or other measures taken to get the traffic we must be prepared. We have prepared ourselves in this respect, that we are going to see what the value is of this great service, I may call it, which we have built up with these duplicate cables, these duplexed lines, these united administrations, with an experienced staff, and with, at the present time, this business; and we are going to see whether we cannot keep a good proportion of what we have got. If you look at the map, and trace the line, you will see that ours is the cord line—it is the direct line (as he proceeded to point out by reference to the map). It is 2,340 miles shorter to Buenos Ayres than the Central American line, 1,100 shorter to Valparaiso, and 223 shorter to Iquique. We have not buried our heads in the sand, but have kept our eyes pretty well open. We can give a more direct service, which means fewer transmissions, and that means fewer errors. It is not given to mortals to command success; but we have done our best, at all events, to deserve it. I do not think that there is anything more that I need trouble you with. If the dividend is passed it will be paid to-morrow. I now move:—

"That the report and accounts to December 31, 1891, be hereby approved and adopted, and that a dividend of 6s. a share, free of income tax, be declared, making, with the interim dividend paid in November, 4 per cent. for the year 1891."

Mr. C. W. EARLE seconded the motion.

Mr. ENNIS expressed great satisfaction at the course which had been taken by the Directors in regard to the election of Mr. Coppen as a Director. He regarded the Chairman's statement as very satisfactory; but he desired to call the attention of the Directors to the fact that a feeling of resentment existed in the minds of some of the shareholders in regard to the large amounts that have been written off and added to the reserve fund. For the rest, he congratulated the Chairman on his able statement.

Other SHAREHOLDERS addressed the meeting, some of whom expressed the opinion that smaller sums ought to have been carried to the reserve fund than had been done in the last two years.

The CHAIRMAN, in reply, stated that the £26,000 discount represented a charge on their revenue of £1,200 a year for all time, and therefore he thought that the Directors had acted wisely in paying it off. If they had not made the transfers to the reserve fund to which reference had been made it would have been impossible for them to have placed the Company in the strong position they had done by duplicating their lines, or it would have been necessary, in order to attain the same object, to have raised the £50,000 of debentures. Having replied to other points raised by the shareholders, he put the resolution, and it was carried unanimously.

The retiring Directors, Mr. C. W. Earle and Mr. D. H. Goodsall, having been re-elected, Mr. Coppen was unanimously appointed a Director; a further resolution being subsequently passed electing Messrs. Turquand, Youngs and Co. and Messrs. Deloitte, Dever, Griffiths and Co., auditors.

A cordial vote of thanks to the Chairman and Directors terminated the proceedings.

Chelsea Electricity Supply Company (Limited).

The ordinary general meeting of the shareholders in this Company took place yesterday, at the offices, Draycott-place, Sloane-square, under the presidency of Mr. J. Irving Courtenay.

The SECRETARY (Mr. S. J. Cluer) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, the accounts before you represent the result of the second complete year of work; and you will, I think, agree with me that, considering the numerous obstacles a pioneer company is bound to encounter, the result is encouraging. The observations I have to make, and the comparisons I shall offer, will, I trust, confirm you in this opinion. No one who realises the difficulties of working up a business of this nature will be surprised at our not being able to pay a dividend as yet in addition to the debenture interest, but we are now in a fair way of earning some return on the ordinary share capital. The gross revenue is 67½ per cent. more than that for the preceding year, but the gross profits are more than three times as large as those of 1890. These profits have, as you will observe, been mainly used for the payment of debenture interest and the extinction of the suspense account. Now, although the improvement is great, we are convinced that a still greater improvement can be made. Much has already been done of which the benefit is scarcely felt in these accounts, as the alterations put in hand early in the year were not completed until December. The result of this was that during the greater part of last year the work was not only carried on under the old disadvantageous conditions, but the difficulty of supply was also enhanced by the alterations going on at the same time. Notwithstanding these adverse circumstances, the improvement in the last three months of the year as pointed out in the Directors' report, has been most marked, the current having been produced for the last quarter of 1891 at 33 per cent less than the average of the previous nine months. I am, however, happy to say that our resident engineer, Mr. Talbot, has successfully coped with all the difficulties of the situation, and has maintained an efficient supply. I need not go into the details of the capital expenditure, as the items are set forth fully in the balance sheet; but as an indication of the economy with which the capital has been used, I may mention that on December 31st last the expenditure for each lamp installed was only £2. 14s. 6d., and it is now less. During the last two years we have obtained an increase of about 20,000 lamps, the total number now standing at over 30,000. The lamp density in the area supplied by the Company is extremely good. At the end of 1891 there were 4,533 lamps installed for every mile of street in which the mains are laid, or 2·6 lamps per yard. The proportion of houses lighted in the streets in which mains are laid is one-quarter to one-third of the total number of houses. The plant is all in good working order, and the cost of maintenance has been moderate. The maintenance of generating plant is 3 per cent.; of buildings, just over ½ per cent.; of mains, 1½ per cent.; and of meters, 2½ per cent. on the capital expenditure. The maintenance of accumulators and accessories amounts to about 2½ per cent. of the capital expenditure on them; but I may remind you of what I have stated on a previous occasion, that the maintenance of accumulators includes the complete renewal of the plates, which are practically the only parts that wear out. The capacity of the present plant in ordinary weather is over 40,000 lamps; but as, in this part of London particularly, we have to take into account prolonged foggy weather, we have to allow a large margin, which reduces the safe capacity to, say, 33,200 lamps. By an expenditure, however, of about £1,600 this capacity could be increased to 36,200 lamps, and, by laying out a further sum of about £1,000, to 38,350 lamps. The introduction into our system of the continuous current transformer, which was initially arranged as part of the system by Mr. Frank King, and which was viewed by some authorities as somewhat in the nature of an experiment, has proved a permanent success. Apparatus of this class had not previously been used for the purposes of general electricity supply; and it is gratifying to note after two and a-half years' experience that they work most steadily and efficiently, and at a very low figure for maintenance. These are now made by the Electric Construction Corporation at Wolverhampton. We have not carried out the extension of our mains as contemplated when I last addressed you, and, consequently, our income has not been as large as was then estimated. I will now endeavour to give you an estimate of the revenue for this year. Taking only the additions to the lights which we now have in view within our present area, and calculating on the basis of the results of 1891, the gross revenue from current alone should amount to over £13,000, as against £9,681 for 1891, an increase of 34 per cent., without entering upon fresh territory. A profit of 2½d. per unit on this output would realise a sum sufficient to pay debenture interest on, say, £35,000 and a 4 per cent. dividend on the share capital. But we look for still better results. There is yet room for a substantial increase in the number of lamps where the mains are laid; new blocks of houses are rising, and we know of two estates in the neighbourhood of our mains which are about to be rebuilt. As I have before mentioned, nearly all new houses in this district are wired for the electric light. This bears upon a question which has been rather fully discussed—the reluctance to take the electric light among a number of people who do not care to incur the expense of having their houses wired, especially where the leases have only a short time to run. During the first quarter of the year we have obtained an increase of over 2,500 lamps. The revenue account for that quarter fully bears out the estimate I have just given you of the revenue for the current year. Our figures are based on a return per 8 c.p. lamp of 9s. per annum, an amount likely to be increased as more shops and trading premises come on the circuit. We are still giving our close attention to improvements in economy of working, and are continuously taking careful tests of results. The supply has already been acknowledged to be the best for the consumer, and it is second to none in steadiness and in quality; and we believe that a system of supply which is popular with the consumer must succeed in the end in giving satisfactory returns to the shareholders. He concluded by moving the adoption of the report and accounts. (The report will be found below.)

The DEPUTY-CHAIRMAN (Major-General Webber), in seconding the motion, said that owing to the nature of their district their returns must not be compared with those of other Companies supplying, for instance, St. James's or other parts of London, their lights coming on by only twenties and thirties at a time. The Chairman had said that the cost of the maintenance of the accumulators and their accessories had been only 2½ per cent. That was the case as regarded the past year; but he believed the average would be between 5 and 6 per cent. per annum, though that would be regarded as very moderate by all electrical engineers.

The CHAIRMAN, in answer to a question, said the meeting had been called at their offices and central station, where they had a suitable room for holding it; and they therefore thought it was unnecessary to go to the expense of meeting at a place in the City. In his remarks on the cost of maintenance of accumulators and their accessories he had referred to the past year only, and what he had said was precisely the case. Each year, of course, must take care of itself. What they would do with regard to the accumulators was not to estimate, and put down something for depreciation; but they would put in new plates and keep up the whole of the batteries each year as good as new, charging the cost to revenue. He then put the motion, and it was carried unanimously.

Resolutions were afterwards passed re-electing the retiring Directors, Major-General Webber and Mr. Nugent Daniell, and the auditors, Messrs. Cooper Bros. and Co.

A vote of thanks to the Chairman and Directors brought the meeting to a close.

The following is the Directors' report, referred to above:—

The number of lamps installed on December 31, 1890, was 19,580, and on December 31, 1891, 27,500; the number installed at the present time is over 30,000. The gross revenue for the year is £10,172. 10s. 11d., as against £6,079. 12s. 5d. for 1890; and the gross profit for the past year £1,750. 11s. 4d., as against £542. 19s. 5d. for 1890,

Digitized by Google

There has also been a decided reduction in the cost of producing the electricity, but, as the new chimney and the re-arrangement of the plant were not completed until the end of the year, the improvement was obtained only in the last quarter of the year, as the following figures will show. The coal, water, wages, and other running expenses, for the first nine months of the year amounted to 4·5 pence per unit sold, while for the last three months of the year they were only 3·0 pence per unit, or 37½ per cent. of the revenue, and there is every reason to believe that the improvement will continue. The management expenses, including rent, rates, and taxes, now represent 1·9 pence per unit sold, as against 3·0 pence per unit for 1890. The plant is all in good working order, and the mains are in first-rate condition and have given no trouble.

It has not been deemed advisable to make an issue of the Preference capital authorised by the shareholders at their last meeting, but the remaining £10,000 First Mortgage Debentures (part of an issue of £30,000) have been allotted. The money thus raised has been applied to the purchase of a site for an additional storage station, to additions and improvements to generating plant, to enlargements and extensions of mains, and to the building of a second chimney stack.

The Directors have to report the retirement from the post of Managing Director of Major-General Webber, C.B., who retains his seat on the Board as Deputy-Chairman. The retiring Directors are Major General Webber and Mr. Daniell, who, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Brothers and Co., also offer themselves for re-election.

Metropolitan Electric Supply Company (Limited).

The fifth ordinary general meeting of this Company was held on the 6th inst., at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. E. Cunliffe Owen, C.M.G.) having read the notice convening the meeting, the report was taken as read.

The CHAIRMAN: Gentlemen, the resolution that I have to propose is:—

"*That the report and accounts for the year ending December 31, 1891, presented to this meeting, be and are hereby approved and adopted.*"

The DEPUTY-CHAIRMAN (Mr. J. Denison Pender) seconded the motion.

The CHAIRMAN: Gentlemen, before I ask you to approve of that resolution I must give you a *resumé* of last year's work, and I beg that you will be rather indulgent with me to-day if my voice is not quite up to its usual mark. I am just recovering from a 16 days' confinement to my room from bronchitis, which is not a pleasant companion. I am not quite yet restored, though I only want to exercise a little care and prudence to enable me to perform my duties again as usual. When I had the pleasure of addressing you twelve months ago, I was able to report that our installations were all but completed, that our mains extended for 67 miles, and that we had 480 customers upon our books, and that, looking at the rate which we had calculated as being the proper rate that we might possibly earn, we saw the prospect of a good profit. Our position to-day is strengthened because we have now upwards of 1,000 customers upon our books, as against less than 500. Yet these customers are learning how to economise, and their consumption has not been in proportion to their increased number. But we have the satisfaction of having acquired experience, and, after all, our knowledge of electric lighting is based upon the experience we gather from day to day. But taking the consumption from our meters, the probability is that we shall be able to supply double or even more than double the number of lights we originally contemplated, so that all the expenses in connection with the production of the light have been, I may say, already incurred. And what we want now is more customers, rather than a larger rate of consumption from our present number. At all events, we are not depending upon that, but upon additional customers, because I would rather see our return based upon 5,000 customers than upon 2,000 customers. So that what we want now is to exercise patience and to push our business. We are a paying concern. It is growing every day, and while we are passing through very much the same phase that the gas and telegraph companies passed through—which latter companies have been passing under my own eye—I can see that there is a very satisfactory future before us, a satisfactory future to those who stand by the Company, and that there will also be a growing dividend. We did not contemplate Paddington in our first outlay, and therefore we have exceeded our capital expenditure by about £50,000. But in this case we have brought a very important district into our system, one which is likely to prove valuable in the future: but concerns like this must grow, and when we have secured for it an amount of custom, to take up all the light that we can produce, it will then turn out a very important installation indeed for the Company. I think it will be right to give you at the present moment an idea of the position of our Company as compared with the other companies. The lamp connections of the companies supplying the metropolis on January 1 last was, I am informed, as follows: London Electric, 36,000; Westminster, 62,000; Kensington and Knightsbridge, 38,000; Pall Mall and St. James's, 38,000; Chelsea, 28,000; House-to-House, 19,000; Notting Hill, 3,000; ourselves, 82,000, and we have since increased to 97,000. This morning, too, I find that in the last three weeks we have had applications for 5,103 lamps, which is the largest number we have ever obtained in the same time. You therefore see that we have got everything ready to supply the public, and we have the public almost clamouring to get our light. All that we want now is patience. Our stations have worked in a highly satisfactory manner; our mains have worked without hitch or breakdown; we have 122 miles of mains. There has been, unfortunately I think for electric lighting, a great deal of speculation—speculation not in money nor speculation as far as lighting is concerned, but speculation as to the best and cheapest mode of producing the light. We have not been in this speculation. We have built this system up so that it can be worked out solidly, and we have, I believe, the most complete and most economical system of electric lighting that exists in London at the present time. I have a great deal of sympathy with those who have spent their money to little or no purpose, and who have put too many eggs in one basket. That has not been our principle, quite the reverse; but still it would have been a grand step in electrical science if we could have recognised in some of these great ideas a financial success. I fear, however, that for the moment that is not the case, while what has been done in this respect reflects to a certain extent on the industry generally. I feel that as far as this Company is concerned we stand in a very strong position, for we have proved our system, and are now a paying concern. I suspect that for the moment disappointment has more or less affected the general body of the electric lighting companies' shareholders, but I may say that it has not shaken my belief in the future of the electric light; and as London and its suburban population is about the least well supplied any of the large cities in Europe, I consider that the field is only beginning to be occupied, that it is a very wide field, and when it is occupied it will be a very remunerative field indeed to those who have the courage to watch its progress with patience and stand by it. I shall not trouble you by going into the accounts. Our accounts are made up in accordance with the requirements of the Board of Trade. You have them before you. They speak for themselves. They have been superintended and approved by your auditors, Messrs. Deloitte, Dever, Griffiths and Co.; and if any gentleman wishes to put any questions to me on the subject, I shall be very pleased to answer him. As I have already said, we shall want a certain amount of additional capital, and we propose to raise that capital, as it will be only temporary, by the issue of £100,000 of debentures. We shall issue these debentures *pro ratâ* to the shareholders at par, and in amounts to meet the smallest investors. We think them very good indeed and that we are offering a plum to every investor in this Company, while we are giving a rate of interest which I consider rather a high rate under ordinary circumstances. Still, the amount is small, and I want to show the shareholders that we are in touch and in sympathy with them, and I wish to encourage them to go on by giving them a little better debenture than they could get elsewhere. In my opinion they could not get a better debenture than the one we are offering.

A SHAREHOLDER: What is the rate of interest?

The CHAIRMAN: Five per cent. I have stated before that when we get our present system into complete working order it will only be the beginning, I believe, of what will be a very extensive system indeed. We are not, however, going to run any risks. We are going to satisfy ourselves thoroughly: to nurse what we have got, which is good, and to nurse it to a point which will enable us to say that we will go ahead. In that case we shall require more money, and then we can deal with the whole of this £100,000 of debentures. At the outset, however, we do not expect to require more than £50,000, so as to enable us to complete our Paddington station. We shall then rest and watch our progress; and I hope when I meet you in another year I shall be able to show you that we have doubled the number of our customers again, as we have done in the past year. With these remarks I beg to move the adoption of the report and accounts. I have read the resolution, and it has been seconded by Mr. John Denison Pender.

A SHAREHOLDER inquired whether the residue of the ordinary shares offered last year had been taken up.

The CHAIRMAN replied in the affirmative, and expressed his readiness to answer any further questions. No shareholder, however, rising to address the meeting, he put the resolution, and declared it carried unanimously. Continuing, he proposed the next resolution, as follows:—

"*That a final dividend of 2s. per share on the whole of the ordinary shares of the Company be and the same is hereby declared, such dividend to be payable on May 14, 1892, to all holders on the Company's register on April 30, 1892.*"

Admiral Sir GEORGE H. RICHARDS, K.C.B., F.R.S., seconded the motion, which was carried unanimously.

The CHAIRMAN then proposed the re-election of the retiring Directors, Mr. J. Denison Pender, Admiral Sir George H. Richards, and Mr. John Benjamin Verity.

Sir JAMES ANDERSON seconded the resolution, which was carried unanimously.

The election of the retiring auditors, Messrs. Deloitte, Dever, Griffiths and Co., was afterwards proposed and carried unanimously.

Sir THOMAS BAZLEY inquired whether any depreciation had been allowed for on machinery and on the accumulators.

The CHAIRMAN replied when he entered the concern he felt that the responsibility of the accounts must always rest upon their auditors; and as Mr. Griffiths was present he would request that gentleman to answer the question. The principle of writing off was a sound one, and one which would be dealt with as soon as practicable. He might, however, state that the Board of Trade was a very wholesome check upon them.

Mr. GRIFFITHS stated that no reserve had been made for depreciation on machinery or plant in the accounts this year. He thought that shareholders would admit, in the case of a company which was practically in its infancy, and had not by any means yet reached its power of work that it would be hardly fair, with so small a revenue as at present, to charge any depreciation. As a matter of fact, however, all expenses on repairs and renewals were charged against revenue.

Sir THOMAS BAZLEY said he thought that the machinery and plant were not worth the sum they stood at, and he considered that the depreciation ought to have been charged against the revenue account.

The CHAIRMAN replied that that was a matter of opinion. For his own part he certainly thought, as the auditor had said, that the time had not yet come when they would be justified in beginning to write off for

Digitized by Google

depreciation. When the proper time arrived the shareholders might rely upon it that this was a matter which would be attended to, as has been done in the case of all the other companies with which he was connected.

A SHAREHOLDER inquired what was the utmost capacity of the present machinery in the way of lighting?

The CHAIRMAN replied that he believed the capacity was now about 250,000 lamps. Judging, however, from the way in which people were beginning to understand the electric light, he would not be astonished if they could supply a much larger number. A year ago the idea was put forward very strongly by the Chairman of the London Company that £1 per light was too little; but if the Metropolitan Company had been earning £1 a light on their 100,000 lamps they would now be paying their shareholders a very considerable dividend. They were now going for a much larger number of lights at a smaller price, and he thought that their average price would be more nearly 10s. per light than £1. In that case, however, they would get their business on a sounder and broader basis.

A SHAREHOLDER inquired whether the Company had power to lay on the wires to houses requiring the light.

The CHAIRMAN stated that they had the power, but there was a large number of firms engaged in the work of installation. If their Company entered on the work they would become to some extent monopolists, and they would have all this particular trade against them. That would not be desirable. It would also require a very large additional capital to carry out the work; and, all things considered, he thought it was better to let this work be done by others rather than by themselves.

A SHAREHOLDER observed that one of the Directors was engaged in the work of installations, and if it paid him would it not be to the interest of the Company to take part in the work also?

The CHAIRMAN stated that they were not prepared at present with the additional capital. They had the benefit of Mr. Verity's experience as to all this particular class of work. He believed that the work which was done by that gentleman's firm was first class. The more, however, that the Directors had looked into this matter, the more they had satisfied themselves that they had better not interfere with the general trade that was engaged in it. He stated at their meeting a year ago that he had been surprised, in driving along Oxford-street, to find that the electric light was so little used. However, its cleanliness, purity, and conveniences generally, were so marked that when people began to use the electric light they did not give it up. It was, he believed, more expensive than gas, but there were some gentlemen who were very acute who used the light—lawyers for instance, whose bills came to only a few shillings a year, for which they had all the advantages to which he had referred. There were other people who had 400 or 500 lamps, but they went away for six months of a year, and in their absence the light was not used. The Company had all these things to contend against. It was a new business, but, as he had said, it was growing day by day, and those who had the courage to stand by it would have their reward. He had been very glad at the discussion which had taken place, for he wanted the shareholders to be satisfied on every point.

A SHAREHOLDER asked whether there was any probability of any of the parishes taking the Company's lighting for the streets.

The CHAIRMAN replied that Mr. Claremont informed him that negotiations were going on at the present time in regard to this matter.

The Rev. WALKER FLOWER afterwards proposed a vote of thanks to the Chairman and Directors.

The motion was seconded and unanimously adopted.

The CHAIRMAN, in acknowledging the vote, admitted that he was a little disappointed at not having been enabled that day to announce a better dividend. He had thought that by doubling the number of their customers they might double the amount of their dividend; but he had mentioned the reasons why they had not succeeded in this. Those reasons were perfectly satisfactory to himself, and he was convinced that, as their customers were increasing, their dividend would improve, while their expenses, he reminded them, would not proportionately be greater. They had a good concern, and all that was required on the part of the shareholders was patience.

The proceedings then terminated.

Oriental Telephone Company (Limited).

An extraordinary general meeting of the members of the above Company was held at the offices of the Company, 14, Austin Friars, E.C., yesterday, Mr. William Addison in the chair. We have been favoured with the following report of the proceedings:—

The SECRETARY (Mr. Alex. B. Chalmers) read the notice convening the meeting.

It was moved by the CHAIRMAN, seconded by Mr. B. ST. JOHN ACKERS, and unanimously resolved:—

"*That the following resolution, passed at the ordinary general meeting of the Company held on the 27th April, 1892, be confirmed as a special resolution, viz., 'That the name of the Company be changed to The Oriental Telephone and Electric Company, Limited.'*"

West India and Panama Telegraph Company (Ltd.)

The following report of the Directors of this Company for the half-year ended December 31st last has been issued, and will be submitted to the thirtieth ordinary general meeting, to be held at Winchester House, E.C., on Tuesday, the 17th inst., at 2 p.m.:—

The Directors submit the accounts (which accompany the report) for the six months ended December 31, 1891. The amount to credit of revenue is £36,141. 2s. 8d., against £43,978. 19s. 8d. for the corresponding half-year of 1890, and the expenses have been £25,296. 3s. 11d., against £21,898. 3s. 11d. for the same period in 1890, leaving a balance of £10,844. 18s. 9d., which, with £5,255. 10s. 2d, brought from last account, makes a total of £16,100. 8s. 11d., with which it is proposed to deal as follows:—

	£	s.	d.
First Preference Shares—			
Dividend, 6 months to Dec. 31st, 6s. per share	10,368	18	0
Second Preference Shares—			
Dividend, 6 months to Dec. 31st, 6s. per share	1,400	14	0
Ordinary shares—			
6d. per share (free of income tax)	2,208	0	6
Balance to current half year's account	2,122	16	5
	£16,100	8	11

The traffic receipts for the six months show a decrease of £7,350. 15s. 8d., as compared with the corresponding period, due to the reduction of tariff, and to the condition of West India trade mentioned in the last report.

As anticipated, there has been an increase in the cost of repairs to cables, which amounts this half-year to £15,056 (as compared with £9,155 for the corresponding period). Of this sum £2,119 has been taken from the reserve fund.

The laying of the new cable between Trinidad and Demerara was completed by the Company's s.s. "Grappler" on November 18th last, thus affording duplicate telegraphic communication to the latter colony. All the colonies served by this Company are now connected by double lines of cables.

In exercise of the authority conferred upon the Board by resolutions passed at the ordinary general meeting of the Company, held on May 13, 1891, debentures to the amount of £80,000 (part of the £100,000 thereby authorised) have been issued at par, bearing 5 per cent. interest as from January 1st last. This issue has been applied to the payment of the £50,000 debentures, which fell due on December 31, 1891, and for the part payment of the St. Vincent-Barbados and Trinidad-Demerara duplicate cables.

In accordance with the Articles of Association, Henry Holmes, Esq., and Henry Weaver, Esq., retire at this meeting, and offer themselves for re-election. John George Griffiths, Esq., the auditor, also retires, and offers himself for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

ABELL'S ELECTRICAL ENGINEERING COMPANY (LIMITED).—This Company was registered on the 3rd inst., with a capital of £5,000, in £5 shares. The objects are to purchase or otherwise acquire the business of electrical engineers and machinists, now carried on by Thomas K. Abell, of The Stoops, Rainhill, Lancs., and William Hughes, of New Cross-street, St. Helen's, electricians, under the style of "Abell and Hughes," at the Steam Factory, Raglan-street, St. Helen's, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, manufacturers of electrical apparatus, machine and engineering tool makers, boiler makers, iron founders, &c. The signatories are:—

	Shares
Thomas K. Abell, The Stoops, Rainhill, Lancs., electrician	65
William Hughes, 22, New Cross-street, St. Helen's, electrician	55
P. B. Glover, Lime Grove, St. Helen's, mining engineer	50
James W. Glover, St. Ann's, St. Helen's, mining engineer	30
Samuel Urmson, Cowley Hill-lane, St. Helen's, colliery proprietor	20
W. J. Glover, The Ropery, Liverpool-road, St. Helen's	20
James Hodson, The Ropery, Liverpool-road, St. Helen's	20

Registered without Articles of Association.

MATHER AND PLATT (LIMITED).—This Company was registered on the 4th inst., with a capital of £200,000, in £10 shares, by Cooper, Dennison, and Co., 5, Shoe-lane, E.C. The objects are to acquire and take over as a going concern the business of steel and iron founders, mechanical and electrical engineers, and millwrights, now carried on by Messrs. William Mather and John Platt, at the Salford Iron Works, Salford, Lancashire, under the style or firm of Mather and Platt, and all or any of the assets and liabilities of the proprietors of that business in connection therewith, with a view to the above objects, to enter into and carry into effect an agreement which has already been prepared, and is expressed to be made between the said William Mather and John Platt of the one part, and the Company of the other part (a copy whereof for the purposes of identification has been subscribed by Edward Boutflower, solicitor), and to carry on the business of mechanical, electrical, and hydraulic engineers, manufacturers of machinery, tool makers, boiler makers, steel, iron, and brass-founders, metal workers, millwrights, machinists, electricians, iron and steel converters, chemists, metallurgists, &c. The signatories are:—

	Shares
William Mather, Salford Iron Works, Manchester, engineer	1
John Platt, Salford Iron Works, Manchester, engineer	1
Edward Hopkinson, Salford Iron Works, Manchester, engineer	1
Colin Mather, Salford Iron Works, Manchester, engineer	1
Thomas Thorp, Salford Iron Works, Manchester, engineer	1
John Milligan, Salford Iron Works, Manchester, engineer	1
Andrew W. Manson, Salford Iron Works, Manchester, cashier	1

William Mather, John Platt, Edward Hopkinson, and Thomas Thorp are to be the Managing Directors, and the two former shall each be entitled to hold office during his life, provided he holds not less than 1,000 shares, and the two latter so long as each holds 250 shares. William Mather shall be the governing Director, and shall have paramount authority so long as he holds not less than 1,000 shares. A sum not exceeding £4,000 yearly shall be appropriated as salary for the Managing Directors. In the

Digitized by Google

absence of William Mather, the rights, powers, and authorities given to him (except the power of removing a Managing Director) may be exercised by John Platt, and after William Mather has ceased to be a Director, the powers, rights, and authorities given to him shall be exercisable by the said John Platt and Edward Hopkinson jointly. Every Managing Director shall hold not less than 250 shares, and every other Director not less than 100 shares. William Mather is the governor of the Company and Chairman of the Board so long as he remains a Director and is willing to act, and John Platt the Deputy-Chairman. When the said William Mather ceases to be the Chairman, John Platt shall, if then a Director, become Chairman and Edward Hopkinson Deputy-Chairman of the Company.

MISCELLANEOUS.—British Seamless Steel Tube Company (Limited); capital £20,000, in £10 shares and 100 £1 founders' shares.

BRITISH ELECTRIC TRAMWAYS AND GENERAL SYNDICATE (LIMITED).—In reply to inquiries made on March 9th last, as to whether the above-named Company was still in operation, a reply was received stating that a meeting of the Company was to be held in a short time, and the returns for 1890, 1891, and 1892, have now been filed. The annual return for 1890, made up to December 31st of that year has been filed. The Company was registered on December 15, 1888, with a capital of £10,000, divided into 1,850 "A" shares (which are entitled to an £8 per cent. Preferential Cumulative dividend), and 150 founders' shares of £5 each. At the time of making up the 1890 return, only seven "A" shares and 87 founders' shares were taken up, and upon all the founders' shares the full amounts had been called, and all calls (£435) had been paid, while upon the ordinary shares no calls had been made. The return for 1891, made up to December 31, 1891, and the return for 1892, made up to April 22nd, give similar results. Registered office: 81, Gracechurch-street, London, E.C.

ELECTRICAL WORKS, CONSTRUCTION, AND MAINTENANCE COMPANY (LIMITED).—The annual return of this Company, made up to December 31, 1891, was filed on April 13, 1892. The Company was registered on March 2, 1888, with a nominal capital of £2,000, in £1 shares, with objects as indicated by the title. At the time of making up seven shares had been taken up, upon which no calls had been made. The shareholders include James Whitehead (electrical engineer) and Robert Hammond (electrical engineer). No agreements for the acquisition of contracts, businesses, plant, &c., have been filed. Registered office: 15, St. Helen's-place, E.C.

ELECTRICITY AND ELECTRICAL ENGINEERING NEWSPAPER COMPANY (LIMITED).—The first annual return of this Company has been filed, showing that all the shares are taken up and fully paid.

HOBART TRAMWAY COMPANY (LIMITED).—Particulars respecting this Company appeared in *The Electrician* for March 11th; and in reference thereto an agreement was made on December 18, 1891, by which the Hobart Tramway Company of Hobart, Tasmania, agreed to hand over to the English Company the tramways, works, stock, and assets, complete to the satisfaction of the local authorities, and in a fit state to be handed over to Messrs. Siemens Bros. and Co. (Limited) for working the same. The consideration given to the Tasmanian Company by the English Company was £20,000 in paid-up ordinary shares and £35,000 in cash. By an agreement made March 24th last, a modification was made in the first-named agreement, by which the £35,000 to be paid in cash was altered to £25,000 in fully-paid shares, and £10,000 in First Mortgage Debenture Bonds.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY (LIMITED).—The annual return of the above Company, made up to March 8th last, was filed on the 5th inst. The nominal capital is £812,000, in £10 shares, of which 41,600 have been taken up, the full amount called, and all calls paid.

JOHANNESBURG LIGHTING COMPANY (LIMITED).—The statutory return of the above Company, made up to March 24th last, was filed on March 30th. At the time of making up 8,400 preference and 17,570 ordinary shares had been taken up, all of which had been given in exchange for debentures in the late South African Company.

LIVERPOOL HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—The annual return of this Company, made up to January 11th, was filed on April 30th. The Company was registered in June, 1889, with a capital of £100,000, divided into 19,900 ordinary and 100 founders' shares of £5 each. At the time of making up 107 (100 founders' and seven ordinary) shares had been taken up, the founders' shares being issued as fully paid to the parent House-to-House Company. Upon the ordinary shares no calls have been made.

PHOSPHOR BRONZE COMPANY (LIMITED).—The annual return of this Company, made up to April 1, 1892, was filed on April 21. At the time of making up, 7,335 ordinary and 8,375 preference shares had been taken up, the full amount called, and all calls (£78,550) have been paid. £90 has been paid on 18 ordinary and 18 preference shares forfeited.

SUNDERLAND AND DISTRICT ELECTRICITY SUPPLY COMPANY (LIMITED).—A letter from the solicitors to the above Company states that "nothing has been done since its registration, and that no business has been commenced." The Company was registered on February 13, 1889, with a capital of £100,000.

WARD ELECTRIC CAR COMPANY (LIMITED).—The annual return of this Company, made up to January 13th, was filed on March 7th last. The Company was registered on October 2, 1888, with a capital of £300,000, in £10 shares, to enter into and carry into effect an agreement with Michael R. Ward for the acquisition of certain letters patent, and to carry on the business of manufacturers of, and deal in, all things capable of being used in connection with the generation, distribution, supply, accumulation, employment or utilisation of electricity. The patents sold to the Company were No. 4,533, of 1887, and Nos. 2,876, 6,927 and 6,938, of 1888. At the time of making up all the shares had been taken up, and all issued as fully paid.

WILLANS AND ROBINSON (LIMITED).—The annual return of this Company, made up to April 20, 1892, was filed on April 25th. At the time of making up 2,200 shares had been taken up, of which 980 had been issued as fully paid. Upon 1,213 of the remaining shares the full amounts have been called, £30 on one share, £20 on six shares, resulting in the payment of £60,740, and leaving a call of £10 per share on six shares unpaid.

WOKING ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to November 19, 1891, was filed on March 22nd last. At the time of making up 2,112 shares had been taken up, of which 2,000 had been issued as fully paid, to the Electric Trust (Limited). Upon the remaining shares 25s. per share has been called, resulting in the payment of £85, and leaving £50 as yet in arrears. By an agreement made April 12th last between the Company and the Electric Trust (Limited) it is stated that the Woking Company was indebted to the Electric Trust for work done and goods supplied, and that the Electric Trust had consented to accept 843 shares in the Woking Company in payment of such indebtedness; it was therefore agreed that the Woking Company should forthwith issue to the Electric Trust 843 shares, Nos. 2,113 to 2,955, credited as fully paid up. Registered office: Board School Road, Woking.

CITY NOTES, &c.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—Particulars will be found in our advertising columns of the first drawing of 549 debentures of £100 each in the above Company. The debentures will be paid off at par on July 1st next, at the Alliance Bank, Bartholomew-lane, E.C., after which date interest ceases.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The following circular has been issued to the shareholders of this Company:—"You will no doubt have seen in the papers the prospectus of the South American Cable Company (Limited), and observed that it is based upon the annual returns of this Company for the past 5½ years. As this is so I would point out that the figures given in the prospectus as this Company's income from the South American traffic include, in fact, the Company's traffic from the West Coast of Africa and the Cape Colonies, which is not an inconsiderable item, and which cannot accrue to the new Company. It will be remembered that for some time past the South American traffics have been abnormally high, owing to a series of political and financial disturbances in various Republics of South America. With a more settled condition of affairs the traffic has now fallen to a more normal state, which resulted in the half-year ended December, 1891, in a receipt of £125,244, and for the period from January 1st last to date it has been at the rate of £109,000 for the half-year, as compared with £170,026 given in the prospectus for the corresponding half-year of 1891. The estimate, therefore, of traffic to a competing company, taken on the basis of £170,026, must be reduced by at least one-third. You will no doubt have also noticed in the public prints the intimation of the reduction of rates over the competing existing line *vid* Galveston and the West Coast of America. This reduction the Company have now to face, as well as any other reduction which might follow from the laying of an additional cable, and the competition of the Antilles cable when completed, all of which must materially and adversely affect the prospects of the new Company as set out in the prospectus. It is not apprehended that these circumstances will so prejudicially affect this Company as they must any competing line, the Brazilian Company having a joint purse agreement with the Western and Brazilian Telegraph Company, who cover the collecting ground for messages from Brazil and the East Coast of South America. Moreover, this Company have two cables between Lisbon and Pernambuco, and the duplication of the Western Company's line from Pernambuco to the River Plate will be completed in the course of a few days. Your Directors, therefore, consider that the revenue of £85,000 per annum which the new Company anticipates from their single cable is considerably over-estimated. Your Directors think it right that you should have this information before you, as they consider that whilst the new Company may prejudicially affect your interests, that Company will be unable to reap a corresponding advantage to themselves; and your Directors, therefore, recommend that you should not support the new enterprise.—By order, Richard Collett Secretary."

CALLS DUE.—Exeter Electric Light Company (Limited): 25 per centum on 10,000 £5 per cent. First Mortgage Debentures (*May 21*).—India Rubber, Gutta Percha, and Telegraph Works Company (Limited): £5 on 8,400 new £10 shares (*May 14*).

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended May 8th were £802, as against £695 for the corresponding period of last year, being an increase of £107. The total receipts to date, from January 1st last, amount to £15,220, against £13,942 in the corresponding period of 1891, being an increase of £1,278.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—The Directors of this Company will recommend to the shareholders at the forthcoming general meeting, that dividends be

Digitized by Google

paid at the rate of £6 per cent. on the preference and £1 per cent. on the ordinary shares, less income-tax paid for the half-year ending 31st March last, making with the interim dividends paid £6 per cent. per annum on the preference shares, and £3 10s. per cent. on the ordinary shares for the year. The transfer books will be closed from the 14th to the 16th inst., inclusive.

MESSRS. T. POTTER AND SONS (LIMITED).—The prospectus is issued of this Company; registered with a capital of £20,000, in £1 shares, to acquire the business of engineers and metal workers, carried on at South Molton-street, Oxford-street, and Hampstead. The Company propose to include electrical engineering in their operations. Application for the whole 20,000 shares is invited. Offices: 361, Oxford-street, W.

SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The Directors of this Company on Tuesday decided to pay an interim dividend at the rate of £8 per cent., free of income-tax, for the half-year ended March 31, to be distributed in accordance with the Articles of Association. The dividends are to be paid on the register as it stood on the 10th inst. The dividend warrants will be issued on the 31st inst. The dividend represents 2s. 9⅔d. per share on the ordinary shares, and 3s. 6½d. per share on the fully-paid shares.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended May 6, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,710.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 731.—Vol. XXIX. FRIDAY, MAY 20, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The system of "Authorised Abstracts" inaugurated by the Council of the Institution of Electrical Engineers at the beginning of 1889 having been discarded, we resume this week, after a lapse of three years, the exercise of our own discretion in dealing with the question. At the date when the Council of the Institution thought fit to exclude reporters, we were in the habit of devoting considerable space to the reports of the discussions. Times have, however, changed since then, and we are now no longer able to give as much space as formerly. We propose, therefore, to publish carefully edited abstracts, and to give the speakers an opportunity of revising their remarks before they appear in print. In so doing we think that we are consulting the best interests both of the speakers, the exact meaning of whose statements when left in all their native vigour is not infrequently obscure, and of our readers, who for the most part have no time to wade through columns of ambiguities.

Among the physical units which have never "caught on" is the lux, partly perhaps because little attention has been paid to the science or art of illumination. When it was proposed by Mr. Preece at the Paris Electrical Congress in 1889 it was avowedly the name for the illumination due to one carcel lamp at the distance of one metre. The continental savants did not seem to appreciate it, and little has been heard of it for some time. At a meeting of the Royal Institute of British Architects on Monday last, Mr. Preece, after tracing the progress of artificial illumination from the time of Ajax to that of the Crystal Palace Exhibition, threw over the old-fashioned French carcel, ignored the scientific and cosmopolitan metric system, neglected a difference of twelve per cent., and brought forward the lux in an English garb as the illumination due to a candle at a foot. There is a purism which revolts at a candle-foot, because some ignorant person might rush to the unnecessary conclusion that, like a foot-pound, it is a quantity consisting of the product of two factors. The merit of the term "candle-foot" is that it is self-explanatory, and in this it resembles the word "pound-degree," which is not misleading, because it contains no allusion to the variation of specific heat with temperature, and which is, moreover, vastly preferable to "calory."

A "rule" was given by Mr. Preece to his fellow architects which may lead them into trouble if too confidently applied. "The great problem for solution was so to diffuse light throughout a room that it should be distributed uniformly over the working surfaces with an intensity of a lux." To do this, Mr. Preece recommended 16 c.p. lamps arranged at the corners of 8ft. squares, and hung 8ft. above the floor. So far, the advice was excellent for those who could afford it. The illumination will be very uniform, and its mean value will be very nearly one lux, according to its latest definition. But Mr. Preece went on to generalise, and discovered a coincidence between the 64 watts which are required to run a 16 c.p. lamp, and the 64 square feet illuminated per lamp, thus arranged. One watt per square foot is a very attractive "rule;" but if the candle-power of the lamp and its height above the ground be left out of consideration, it is as incomplete as a rule that one spoonful of paint should be used per square foot for painting a wall, without specifying the size of the spoon. The colour of the walls and ceiling, by-the-bye, is of about as great importance as the height of the lamp or its candle-power.

Much excuse is to be found for the scientific expert if he flatly contradict the assertions of opposing witnesses when pressed by a bullying or by an ingenious counsel, or when suffering from nervousness, or when drawn by enthusiasm into involuntary partisanship. But it is not easy to pass over completely discordant utterances of prominent scientific men at societies' meetings, especially when no burning argument is being debated, and when the utterances are unsupported by any experimental evidence. These remarks may appear to be a ponderous introduction to the comparison of two statements as to the absorption of light by ground glass; but fuss is made about the 98 or 100 per cent. conductivity of copper conductors, or similar differences in the electrical efficiencies of dynamos or transformers, and the question would be of very considerable interest if electrical engineers were really concerned with the purveying of light. Prof. Forbes gave it as his opinion, rather more than a year ago, that frosted glass absorbs little or no light, and that what is absorbed is due to the dirt which the frosting collects. Mr. Preece, using the expression ground glass, a rather different material, but pointing to the frosted bulbs of the glow lamps in the room of the Royal Institute of British Architects, informed his audience that they absorbed about 50 per cent., and when "a voice" said 60, Mr. Preece willingly adopted the correction. We have criticised Prof. Forbes' statement in these columns, but we are inclined to

Digitized by Google

think that of the two his estimate is very much nearer the mark.

PHOTOMETRIC measurements of absorption by different kinds of glass were made more than ten years ago by Sir JOSEPH BAZALGETTE and Mr. T. W. KEATES for the Metropolitan Board of Works. They found that opal glass absorbed more than 59 per cent. The tests by Mr. GEORGE DEACON for the Liverpool Town Council gave 58 per cent., and those of M. ALLARD, on behalf of the Municipal Council for Paris, 40 per cent., while ground glass was found to cut off 25 to 35 per cent. Ground glass differs very widely in quality; the coarse grinding on a stone, the various degrees of sand grinding and sand blast, probably differ in their absorbing power; the fine grain used for photographic purposes, and the different kinds of etched or frosted glass are all included under the same name. Mr. CONRAD COOKE has found only 13 per cent. absorption in the case of a fine-etched gas globe. A dead-white surface acts as a reflector in a peculiar way. At whatever angle light falls upon it, most light is reflected in a direction perpendicular to it, and at other angles it falls off approximately as the cosine. Ground glass behaves in a somewhat similar way, and light is transmitted through it partly direct and probably partly as the cosine of the inclination with the perpendicular. Both the real loss and the variation in different directions are worthy of attention; and while it is impossible to remove the frosted surface from a bulb, the real absorption of these very attractive lamps ought to be definitely ascertained.

THE fusion of the sciences of electricity and optics which may some day come about, since the identity of light with electro-magnetic vibrations has been definitely proved, does not yet warrant the discussion of purely optical matters in these columns; but researches connected with radiant energy, especially where questions of wave length arise, present considerable interest to students of electrical science; and this is especially the case where radiations of a particular wave length suffer selective screening. In the *American Journal of Science* of the present month an account is given of some researches by Mr. HUTCHINS upon the radiation of atmospheric air. A column of heated air was caused to pass in front of a thermopile, and the radiation from the air alone was measured. So far, the experiments, interesting as they were, have no apparent connection with electrical matters; but it was found that when a very pure plate of quartz 0·5cm. thick was placed over the opening to the thermopile, with the air at 100°, no deflection could be obtained; and even when the temperature was raised to 200° there was no measurable effect. Without the quartz plate the deflection was 151. The quartz plate allows 93 per cent. of the sun's rays to pass it, 31 per cent. of the rays from red-hot platinum, and 3 per cent. of rays from lamp-black surface at 100°, being progressively opaque to waves of increasing length. The waves from heated air must therefore be of great length, since they seem incapable of penetrating quartz to any considerable degree. The question of screening has been attacked by Lord KELVIN, but there is still a lack of definite information about the screening properties of different substances for waves of different lengths. We have already alluded in these columns to the possibility of piercing fogs by radiations having sufficiently great wave lengths to occupy a position midway between ordinary light and those electro-magnetic disturbances with which HERTZ has made us familiar.

IT will be news to most English readers that Mr. EDISON is dissatisfied with American patent law, from which, so says the *Electrical World*, he has suffered so much that, backed by a powerful Telephone Company, he is going to get it altered. Many years ago we predicted that this insatiable patentee would never be content till he had secured a patent in his own favour for exclusive right of patenting; and it seems that he is now about to assert some such pretension, at all events so far as concerns the telephone. The story of the Berliner patent which we recently commented upon, is practically repeated in our "American Notes" this week, with the additional information that the claims are very broad—which means that they cover every existing telephone—and that the law which extinguishes those claims on the expiry of EDISON'S European telephone patents is likely to be rescinded or suspended for another 17 years. Nobody can doubt that at the end of that time the great magician will fetch out another "suspended" patent from up his sleeve, and repeat the operation at pleasure. Happily for us Europeans, his patents cannot be conjured into life again by the same process on this side the Atlantic.

THE address recently delivered by M. SÉRULLAS before the Société d'Encouragement on the subject of gutta-percha cultivation and collection, an abstract of which will be found elsewhere in the present issue, was without doubt suited to his audience. Any programme containing such items as methodical cultivation and thorough utilisation of existing resources and emancipation of a new French industry from foreign influences never fails to prove attractive across the Channel. We sincerely hope that M. SÉRULLAS is right and everyone else wrong; but the mere fact that English cable-makers, who have every inducement to encourage any practicable scheme for preventing the exhaustion of our gutta-percha supplies, should have persistently thrown cold water on M. SÉRULLAS and all his works is, to say the least, significant. An authoritative pronouncement as to the futility or practicability of gutta-percha plantations, and of obtaining *good* gum from leaves or bark, would seem highly desirable.

IN our issue of December 4th, 1891, when discussing the question of English electrical engineering exhibits at Chicago, we hazarded the suggestion that since the Exhibition authorities were so anxious to secure "representative" exhibits, they would do well to obtain a few specimens of good roads from this country. From a note in the *Engineering and Mining Journal* of New York we gather that something of the kind is on foot. One Col. ALBERT A. POPE, of Boston, has written to the Director-General of the Exhibition, "urging that strenuous efforts be inaugurated to make a comprehensive exhibit of improved roads and road-making machinery;" and the Exhi-

Digitized by Google

bition grounds not permitting of sample European roads being laid down, it has been decided to obtain sectional models. If "object lessons" of this description are really to be a feature at Chicago, a new *raison d'être* for these shows will have been found. International Exhibitions will not in future be primarily demonstrations of foreign proficiency in this or that art, but will be devised so as to effectually show up native deficiencies. Solemn fasts, not big feasts, will then appropriately open the proceedings.

The Edison Station in Paris.—On March 31, 1892, the Compagnie Continentale Edison had 43,942 10-c.p. lamps connected to its Paris mains.

Stockholm.—The Town Council have granted a concession for an electric tramway, running to Djursholm. A steam railway on this route had been previously authorised.

Société Internationale des Électriciens.—The President and Council of this Society, mentioned on page 27 of our last issue, are for the year 1893-4, and not for 1892-93, as stated.

The Engineering Exchange.—The Engineering Exchange will be officially declared open in the Exchange Room of the Jerusalem, Billiter-buildings, E.C., on the 31st inst., at 12 o'clock.

The Lighting of the City of Mexico.—The city of Mexico, says *El Telegrafo Espanol*, is lighted by 299 arc lamps of 2,000 candles, 145 arcs of 1,200 candles, 408 gas lamps, and 1,534 oil lamps.

Exeter.—At the last meeting of the Town Council a resolution was passed stating that it was desirable to light the open spaces of the city by electricity, provided it could be done at reasonable cost.

The House of Commons Telephone.—The telephone in use at the House of Commons was on Wednesday for the first time placed in direct connection with Birmingham, and messages were transmitted to that city, Wednesbury, and West Bromwich.

The Electrical Utilisation of Water Power in Switzerland.—A sugar refinery at Monthey, near Vevey, is about to be fitted with two 125 H.P. 1,000-volt continuous-current motors. Power will be derived from a 110ft. fall, about three-quarters of a mile distant.

Cable Interruptions and Repairs:—

	Date of Restoration.
REPAIRS.—Siberian Landlines	May 14, 1892.
	Date of Interruption.
INTERRUPTIONS.—Bolama-Bissao Cable	April 23, 1892.
Mossamedes-Benguella Cable.	May 19, 1892.

Royal Society.—The following Papers were down for reading yesterday:—"On the Changes Produced by Magnetism in the Length of Iron and other Wires carrying Currents," by Mr. Shelford Bidwell, F.R.S.; "On the Measurement of the Magnetic Properties of Iron," by Mr. T. Gray.

Cable Duplication.—The Telegraph Construction and Maintenance Company's s.s. "Scotia" has completed the duplication of the Western and Brazilian Company's Santos-Chuy cable. This completes the direct duplicate service between Brazil and Lisbon, while from the latter place there are triplicate cables to England.

Institution of Electrical Engineers.—A students' meeting was held at the library of the Institution on Friday, 13th inst., Mr. Gisbert Kapp presiding. Mr. Haycroft, hon. sec., read some "Notes on Alternate Current Transformers." At the next meeting, Friday, May 27th, Mr. McDouall will read a Paper on "Electrometers."

Perth (Western Australia).—A report has been presented by Mr. W. J. Hancock (Superintendent of Telegraphs) to the Perth City Council, recommending that a tender by Messrs. Crompton and Co., offering to light the city with 126 20-c.p. incandescent lamps and nine 15-ampere arcs for the sum of £3,750, and an annual charge for seven years of £520, be accepted.

Taunton.—At a meeting of the Town Council last week, held to consider the purchase of the electric light works, there were three special points before the Council for consideration. First, that the Town Clerk be instructed to obtain a Provisional Order; second, that the system of lighting now in use in Taunton be continued for the present; and, third, that a Committee be appointed to negotiate with the Electric Lighting Company, with a view to purchase, on the basis of the report of Mr. Kapp. These three proposals were agreed to.

A Large Electric Locomotive.—According to the *Elektrotechnischer Anzeiger*, MM. Brown and Boveri, of Baden, are about to build a locomotive which will be one of the most powerful in the world, and quite the most powerful of those driven by electricity. It is to be provided with motors of a total horse-power of 1,500, which can be raised to 2,000 horse-power. One motor is placed direct on each of the eight axles, and the locomotive is designed for a speed as high as that ordinarily used on steam locomotives. It is expected that it will be ready to be tested by the end of the present summer.

York.—At a meeting of the Town Council on Tuesday last, a report of the Streets and Building Committee, with reference to the proposed introduction of the electric light by the Corporation, came up for discussion. It was stated that there had been applications for 2,700 lights by private consumers, and that the Corporation would require about 2,500 more. The Committee's report recommending the borrowing of £15,000 for electric lighting purposes was adopted after some discussion. Mr. Crompton was present, and replied to the various questions put to him by members of the Council.

Dundee.—The report by Prof. Kennedy in reference to the proposed municipal central station has just been issued. The engineers are Messrs. Urquhart and Small, and they propose to adopt the three-wire system, with storage batteries As the result of a personal examination of the area proposed to be illuminated, Prof. Kennedy approves of the specifications of the electrical engineers, but suggests that the mains should be continued to the residential district near to the station. At a meeting of the Gas Commissioners on Tuesday, the report was read and adopted, and it was resolved to invite tenders for boilers, steam piping, engines, dynamos, batteries, and mains. The work will be gone on with without delay.

The Electrical Industries in Japan.—A report has just been laid before Parliament, giving the results of inquiries instituted by Her Majesty's Consuls in Japan into the various native industrial enterprises that have sprung up in late years in that country. There are, it is stated, three factories—two in Tokio and one in Yokohama—where insulated and silk-covered wire, incandescent lamps and other goods are produced. According to the report the articles produced are, "on the whole, of very inferior quality, but in many cases their cheapness enables them to compete successfully with goods imported from abroad, chiefly the United States." Dynamos are still imported from America, all attempts to manufacture them on the spot having failed.

Geneva.—M. Turrettini, Director of Public Works to the Geneva Municipality, has just laid plans before that body for a large new hydro-electric installation at Chèvres, on the Rhone, a few miles below Geneva. When complete the station will comprise 15 800 H.P. turbines, only three being immediately contemplated. The total cost is estimated at £225,000. Tenders for the turbines have been asked from Escher, Wyss et Cie., of Zürich, and MM. Faesch et Piccard, of Geneva; tenders for the electrical plant having been asked for from the Oerlikon Works and MM. Brown et Boveri, of Baden. The total capital expenditure of the Geneva Municipality on this and other hydraulic schemee will exceed £400,000. M. Turrettini urges an immediats decision on the Chèvres scheme, in order that the work may be commenced in the autumn.

Accident to the s.s. "Norseman."—A Lloyd's telegram, dated May 13th, off Chuy, states that the "Norseman," belonging to the Western and Brazilian Telegraph Company, which had been engaged with the "Scotia" in duplicating the Santos-Chuy section of the Company's cable, experienced a heavy gale on the 10th, and sprung a leak, which put out the fires. The pumps got choked, and the crew were engaged all day and night baling with buckets, but the water gained. The weather moderated on the 12th, and during the night all hands were transferred to the "Scotia." When left the "Norseman" had 11ft. of water in the engine-room and 3ft. 6in. in the after hold. Later advices state that the "Scotia" towed the "Norseman" to Monte Video, where she arrived on the 16th inst., and having been placed in shallow water, is now being pumped out. It is expected that she will be in dry dock in a few days, when a survey will be held.

The "Board of Trade Unit."—With reference to Lord Kelvin's letter in our last issue, Mr. Binswanger writes that he considers the word "unit" extremely misleading and likely to give rise to confusion. All other electrical units of measurements have received short and appropriate names, says Mr. Binswanger. Why make an exception of the kilowatt-hour? As an instance of the misunderstanding arising out of the use of the word "unit," our correspondent cites the following:—"Meter dials are all divided into multiples of tens, and are logically and grammatically denominated units, tens, hundreds, and so forth. But as meters' indications have generally to be multiplied by constants, and, as is mostly the case, each stroke on the dial denotes one ampere-hour at 100 volts, or one-tenth of a supply unit, it is clear that we shall lead consumers into confusion by printing on the first dial 'units,' whilst it really represents only one-tenth of a Board of Trade Unit."

Obituary.—We regret to record the death of Mr. William Ford, barrister-at-law, which took place at his residence in London on the 14th instant. The deceased gentleman was for many years connected with submarine cable companies, and was a Director of the Globe Telegraph and Trust, the Direct United States Cable, and the West India and Panama Telegraph Companies. He was much esteemed by his colleagues.—We regret to record the sudden death from heart disease, on the 14th inst., at Singapore, of Captain William Fawcus, of the Eastern Extension Company's cable steamer "Sherard Osborn." Captain Fawcus joined the Eastern Extension Company's service in 1884 as first officer of the s.s. Agnes, and was transferred to the "Sherard Osborn" in 1886; and upon the resignation of Captain Francis Worsley in 1887 he assumed the command of the vessel. Captain Fawcus had much experience in cable repairs, and the last work on which he was engaged was the triplicate cable between Singapore and Penang.

The Chicago Exhibition Telephone Exchange.—A contract for a telephone service has been signed by the Exhibition authorities and the Chicago Telephone Company. By its terms, says the *Western Electrician*, the Chicago Telephone Company agrees to establish a telephone exchange and its American District telegraph service "on the most improved plan" at Jackson Park, to be connected with the exchange system of Chicago, so that for every seven exchange telephone subscribers in the Exhibition grounds at least one copper metallic circuit shall be furnished. Some five and twenty call offices are to be erected in the grounds for the use of the general public. Nothing but long-distance instruments and metallic circuits will be used. It is expected that the long-distance copper line to New York will be ready for use by the time the World's Fair is opened, and connections will be made directly with this line at Jackson Park, independent of the Chicago exchange and the city under-ground system.

Prof. Ayrton.—A complimentary dinner was given to Prof. Ayrton on the 13th inst., at the Holborn Restaurant, to commemorate his election to the Presidential chair of the Institution of Electrical Engineers, and as an expression of admiration from a few of his students. The function was inaugurated under the presidency of Mr. W. B. Esson. During the evening an illuminated vellum testimonial, signed by "old boys," was presented to the Professor. The signatories were:—L. B. Atkinson, Frank Bailey, H. J. Dowsing, W. B. Esson, W. Geipel, Reg. J. Jones, W. M. Mordey, Fras. Mudford, Frank Nalder, J. Probert, A. Reckenzaun, F. M. Rogers, H. W. Sayers, W. B. Sayers, R. Percy Sellon, Albion T. Snell, W. E. Sumpner, Ernest B. Vignoles, R. Mullineux Walmsley, H. D. Wilkinson, and Arthur Wright. Among the guests were Mr. Preece, Prof. Silvanus Thompson, Prof. Perry, Mr. Swinburne, and Mr. F. H. Webb. The dinner was in every way a success, and the "speech time" was one of the liveliest on record in the annals of electrical engineering.

The Electric Supply Rates in Paris.—Many Parisians, more ingenious than honest, have been inspired by the great difference in price of the electric current when used for power and for light with the brilliant idea of installing dynamotors in their houses. According to the *Bulletin International d'Electricité*, the latest advocate of this scheme is M. Laur, a well-known member of the Chamber of Deputies. According to the *cahier des charges* imposed on the electricity supply companies in Paris, the maximum charge for the kilowatt hour is 1 franc 50 centimes for lighting purposes, and 60 centimes for power purposes; so that, making no allowance for the cost of attendance, &c., and assuming that the supply companies all charge the maximum, it is easy to work out that the adoption of a dynamotor of ordinary efficiency would result in a saving of about 30 per cent. As a matter of fact, the prices charged by the various companies are as follows:—Société Edison, 1 franc 23 centimes; Société Parisienne, 1 franc 9 centimes; Société Popp, 1 franc 25 centimes; and Société de la Place Clichy, 1 franc 30 centimes.

Gas Engines for Dynamo Driving.—The German Imperial Continental Gas Association, Dessau, after running dynamos by means of gas motors for five years, tabulates the advantages of the system as follows, says the *Gas World*:—1. Small amount of space required. 2. Small consumption of water: 5 to 6 gallons per horse, or less. 3. No coal to carry: independent of railway station. 4. No smoke. 5. No explosions. 6. Cheaper than steam engines in respect of (1) ground required; (2) relative convenience of gas motors rather than steam engines in a town, whence greater choice of place within a town, and smaller distances to lay cables; (3) gas motors above 100 H.P. being cheaper than steam-engines, boilers, chimneys, &c. 7. Less loss of electricity, because station more favourably situated. 8. Less attendance and wages. 9. Exact control over fuel. 10. More regular working, and greater security of power to meet unforeseen demands. 11. Cost of fuel can be reckoned (the gas company running the electric station) at the full cost price of the gas supply. Gas motors of 120 horse now cost to put up about half what steam engines do; and in the future the price of still larger gas motors may be expected to fall.

The Sawyer Telephone Cable.—In order to produce a telegraph and telephone cable having low inductive capacity and high insulation, and which at the same time should be light, flexible and inexpensive, Mr. W. H. Sawyer, of the American Electrical Works, Providence, R.I., has, says the *Electrical Engineer* of New York, recently devised the following arrangement:—A number of insulated conductors, usually four in number, are woven at regular distances apart with some fibrous material into a continuous flat ribbon, which is then wound into a spiral tube, leaving a central air space. The conductors are so woven with the fibrous material as to form an open-mesh work between the wires, and when the ribbon is twisted into a helical form the wires are all approximately equidistant, thus securing the lowest inductive capacity between them. Upon the spiral tube thus formed is wound a second ribbon, similar to the first, but wound in a reverse direction; thus securing the greatest separation of conductors within the least possible space. In forming the complete cable a number of sections thus constructed are grouped together and inclosed in a lead sheath, or a series of successive ribbons carrying the braided wires may be wound upon the spiral tube until the cable is built up to the desired diameter, and then inclosed in a lead sheath, each ribbon being wound in a reverse direction to that of the underlying section.

Magnetic Iron Rust.—At the recent meeting at Hobart (Tasmania), of the Australasian Association for the Advance-

Digitized by Google

ment of Science, Prof. Liversedge, of the University of Sydney, read a suggestive Paper on the rusting of iron. The author remarked that in books upon chemistry it was usually stated that iron rust was composed of the hydrated sesquioxide of iron; but on examining a very large number of specimens of rust from many different places, and from iron articles of various kinds, and formed under very varied conditions, he found that in almost every instance the rust contained more or less magnetic oxide; indeed, in some cases the rust, although presenting the usual rust-brown colour and appearance, was, when powdered, practically altogether attracted by the magnet. The specimens of rust which first drew the author's attention to this subject were large rust scales obtained from some old tramway metals, which he was led to collect and examine on account of their resemblance to the crust so often present upon metallic meteorites. The production of this magnetic oxide does not seem to have been due to the presence of mill scale, because, when bright iron wire, plates, rods, nails, &c., were artificially rusted in many ways with free access of oxygen, in almost every instance a large amount of magnetic oxide was formed. These observations have some practical bearing upon the problem of the preservation of wrought-iron structures from rust.

American Institute of Electrical Engineers.—The general meeting of this Institute will be held at the Grand Pacific Hotel, Chicago, on Monday, Tuesday, and Wednesday, June 6th, 7th, and 8th. The following are some of the Papers in preparation for that occasion:—"Electric Coal Mining Machinery," by Mr. Elmer A. Sperry; "On the Electro-Magnetic Field," by M. I. Pupin, Ph.D., of Columbia College; "Long-Distance Transmission for Lighting and Power," by Mr. Charles F. Scott; "Electric Heating," by Mr. C. E. Carpenter; "A Dynamo Indicator, or Instantaneous Curve Writing Voltmeter," by Prof. George S. Moler, of Cornell University; "The Magnetic Properties of Sheet Iron," by Mr. Milton E. Thompson, of Cornell University; "A Discussion of Circuits containing Resistance, Self-Induction, and Capacity," by Messrs. Bedell and Crehore, of Cornell University; "A Life and Efficiency Test of Incandescent Lamps," by Prof. B. F. Thomas and Messrs. P. Martin and R. H. Hassler; "Notes on Wiping Contact Methods for Current and Potential Measurement," by Prof. B. F. Thomas; "Series Electric Traction," by Mr. Nelson W. Perry; "Oil *v.* Air as Insulation," by Dr. J. B. Williams, of New York; "On the Electrolytic Refining of Copper," by Lieut. F. B. Badt; "The Photography of Alternating Current Curves," by Dr. Edward L. Nichols, of Cornell University; "The Reversal of Polarity in Plating Dynamos;" also on "Dynamos for Continuous-Current Circuits," by Prof. Harris J. Ryan, of Cornell University. Papers are also expected from Mr. H. Ward Leonard, Mr. Nikola Tesla, and Prof. Elihu Thomson.

Petroleum Engines.—In a Paper on this subject recently read before the Institution of Civil Engineers, Prof. Unwin stated that there was no clear evidence that in this country steam could be produced as cheaply from oil as from coal. In a petroleum engine the thermodynamic efficiency might be expected to be more than double that of a steam engine and boiler. In the Priestman engine a jet of oil, controlled by the governor, and a current of air, were mixed in a spraying nozzle, which reduced the oil to very fine particles. The mixed air and spray were then received in a vaporising chamber, heated by a jacket through which the exhaust of the engine passed. During the suction stroke an additional air supply, also regulated by the governor, entered the vaporiser and drove forward the charge into the cylinder. The charge was compressed, ignited by an electric spark, expanded doing work, and finally was exhausted, the cycle being the same as in the Otto gas engine. In a trial of a 5 H.P. Priestman engine, running normally at 200 revolutions, comparing the fuel consumption with that of a steam engine, and taking 1lb. of oil as equivalent to 1¼lb. of coal, the consumption in the oil engine was equivalent in the respective trials to 1·18, 1·23, and 1·02lb. of coal per B.H.P. per hour. The lowest known consumption of steam in steam engines was 1·245lb. per I.H.P. per hour, in a large triple Sulzer engine. This would correspond to 1·61lb. of coal per B.H.P. On all occasions when Prof. Unwin had had one of these engines under observation, it had been started without difficulty, and worked without any hitch. Amongst the special applications might be mentioned dynamo driving in country districts.

The National Telephone Company and its Sheffield Subscribers.—At the quarterly meeting of the Sheffield Town Council last week, the following letter was read from the General Manager of the National Telephone Company to the Town Clerk:—

'Dear Sir,—I observe from yesterday's Sheffield evening paper that notices have been given of an amendment to certain minutes of you Highways Committee relating to the granting to this Company of certain licences for the laying of telephone wires; and my object now in writing to you is to express the hope that having regard to the fact that a meeting will take place in the course of a few days between the Committee which was appointed at yesterday's meeting of subscribers and the Directors of this Company, the amendment may not be proceeded with. As I explained at the meeting yesterday, the Directors of this Company are fully prepared and intend to meet the wishes of the Sheffield subscribers, and it is quite unnecessary for the Town Council to bring pressure to bear by withholding facilities for the running of wires. I would point out that the Town Council by so doing would not only inconvenience the Company, but also many of their own constituents. It is, of course, a matter of great regret that a tariff has been suggested which meets with such universal disapproval, but I cannot help thinking that the object of the Directors in putting it forward has been greatly misunderstood. It is not now to the point, but in fairness to the Company, I may mention that from the statistics placed before the Board, and gathered from other parts of the country, the Directors believed that the proposed tariff would operate in the interests of the great majority of the subscribers. I can only further add, that the Committee when they meet the Directors will find them willing and anxious to meet their views, and to arrange a tariff which will satisfy Sheffield, and that under these circumstances it is unnecessary for the Town Council to whip a willing horse by denying wayleave facilities. May I ask you to be kind enough, if necessary, to place this letter before your Town Council?"

On Thursday last week Mr. G. F. Preston, district manager of the National Telephone Company, issued a circular withdrawing the obnoxious tariff, promising a revised one, and announcing that subscribers to the National exchange were at liberty to communicate with those on the local exchange and *vice versâ* without extra charge. A few days later the Duke of Marlborough announced that the New Telephone Company proposed shortly to seriously canvass the town.

The Incandescent Lighting of the Chicago Exhibition.—The trouble over the incandescent lighting contract for the World's Fair is by no means over, says the *Western Electrician*, in its issue of May 7th. At the time that the Committee on Grounds and Buildings decided to give the work to the Thomson-Houston-Edison Company at its last offer of $5·95 per lamp, nearly everybody considered the matter as settled. But the contract was not signed, and when Mr. Westinghouse reappeared on the scene, the whole subject was left to the discretion of Mr. Higinbotham, vice-president of the Exposition Company. On Tuesday morning, May 3rd, Mr. Higinbotham made up his mind as to his duty in the matter. To a representative of the *Western Electrician* he said: "I have come to the conclusion not to comply with the recommendation of the Committee on Grounds and Buildings, and sign the contract. I shall do my duty in the matter by reporting to the Committee this afternoon in favour of re-advertising for bids. I think that the Committee on Grounds and Buildings should begin all over again." Mr. B. E. Sunny, Western manager of the Thomson-Houston Company, characterises the proposition to re-advertise for bids as "extraordinary," and says: "The matter was settled three weeks ago by a formal resolution of the Grounds and Buildings Committee. We were given the contract, and it does not seem to me possible that the Committee can go back on its action. Such action would be contrary to all business principles. I do not know what we shall do in the event that the Committee takes action with a view of reversing its decision." There appears to be but little doubt, says our Chicago contemporary, that, whatever the result to the electric companies, the World's Fair will get its incandescent light at a very cheap rate. One feature of the situation is the possibility that the Edison Company may seek legal means to prevent the World's Fair from using incandescent lamps of other than its own manufacture, if the Westinghouse Company should get the contract.

TRANSFORMER DESIGN.*

BY DR. J. A. FLEMING, M.A.

We may now consider the full specification for a transformer. Let it be required to design a transformer, say, for transforming W watts of electric power from a pressure of E_1 volts to one of E_2 volts. Required to find the sizes of wires and numbers of turns of the two circuits, and the size of the core and waste of energy in it, under the conditions that the maximum induction density in the core shall not exceed B C.-G.-S. units and the current density in the circuits not exceed 1,000 amperes per square inch. Let other limitations imposed be that the waste of energy in the copper shall not be more than 2 per cent. of the full load.

Since the transformation ratio and power are known we may take it that approximately the full-load primary current will be $\frac{W}{E_1}$ amperes, and the full-load secondary current a little less than $\frac{W}{E_2}$ amperes. Let I_1 be the $\sqrt{\text{mean}^2}$ value of the full load primary current and R_1 the resistance of the primary circuit, and let I_2 and R_2 be the same quantities for the secondary circuit. Furthermore, let N_1, N_2 be the number of turns of wire on these circuits, and l_1 l_2 the lengths, and σ_1, σ_2 the cross-sections of these wires.

At full load the total rate of dissipation of energy in the copper circuits is

$$I_1^2 R_1 + I_2^2 R_2 = K D.$$

But, $$R_1 = \frac{\rho l_1}{\sigma_1} \qquad R_2 = \frac{\rho l_2}{\sigma_2}$$

where $\rho = \frac{16}{10^7}$ ohms, or is the specific resistance per cubic centimetre of copper at ordinary temperatures—that is, the resistance of one cubic centimetre in ohms across opposed faces. Substituting these values of R_1 and R_2, we have

$$D = \frac{I_1}{\sigma_1}\rho I_1 l_1 + \frac{I_2}{\sigma_2}\rho I_2 l_2 \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Now $\frac{I_1}{\sigma_1}$ and $\frac{I_2}{\sigma_2}$ are the current densities in these wires. This current density ought not to exceed 1,500 amperes per square inch, or 240 amperes per square centimetre.

Put, therefore, $$\frac{I_1}{\sigma_1} = \frac{I_2}{\sigma_2} = 240,$$

and we have

$$D = \frac{240 \times 16}{10^7}\{I_1 l_1 + I_2 l_2\} \quad . \quad . \quad . \quad . \quad (2)$$

But in practice $I_1 l_1$ will always be nearly equal to $I_2 l_2$. Hence we arrive at

$$D = \frac{868}{10^6} I_1 l_1 \quad . \quad . \quad . \quad . \quad . \quad (3)$$

$$\left.\begin{aligned} \text{therefore} \quad l_1 &= \frac{10^6 D}{868 I_1} \\ \text{also} \quad \sigma_1 &= \frac{I_1}{240} \\ \text{and} \quad R_1 &= \frac{16}{10^7}\frac{l_1}{\sigma_1} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (4)$$

These last three equations give us the length, section, and resistance of the primary wire when we know the full load primary current and the total power, D, permitted to be dissipated in the copper circuits when the transformer is fully loaded.

For example, let us take the case of a 30 H.-P. closed-circuit transformer and find all the quantities.

The full load of the transformer is 30 H.-P. = 22,400 watts. Suppose, as most likely, that 300 watts, or say, 1·3 per cent. of the full load, is to be allowed to be wasted in the copper circuits at full load, and that the transformer is to be designed for converting from 2,000 volts to 100. Then the full load primary current I_1 is 12 amperes. Therefore we have

$$l_1 = \frac{10^6 \times 300}{868 \times 12} = 30{,}000 \text{ centimetres.}$$

$$\sigma = \frac{12}{240} = 05 \text{ square centimetre.}$$

$$R_1 = \frac{16}{10^7}\frac{l_1}{\sigma_1} = 96 \text{ ohm.}$$

This gives us the length, section, and resistance which the primary circuit ought to have. Having found the dimensions of the primary circuit, we may obtain approximately those of the secondary by the division of l_1 by the transformation ratio $\frac{E_1}{E_2}$ and multiplication of σ_1 by the same fraction. Thus for the above transformer, the length of the secondary will be 1,500 centimetres, and its section 1 square centimetre, and its resistance ·0024 ohm.

The next step is to find the dimensions of the magnetic circuit. These are easily found, thus:—The primary electromotive force is to have a $\sqrt{\text{mean}^2}$ value in volts equal to E_1. Hence, its maximum value is $\sqrt{2}\,E_1$. If the maximum value of the induction density is **B**, and if S is the cross-section of the magnetic circuit, then the value of the quantity $p\,\mathbf{B}\,S\,N_1$ is always nearly equal numerically to $10^8\sqrt{2}\,E_1$, where $p = 2\pi n$ and N_1 is the number of primary turns, and **B** is measured in C.-G.-S. units. Hence,

$$S N_1 = \frac{10^8 \sqrt{2}\,E_1}{p\,\mathbf{B}} \quad . \quad . \quad . \quad . \quad . \quad (5)$$

If we suppose the cross-section of the magnetic circuit to be a square, whose side has a length $\sqrt{S}$, then, since l_1 is the length of the primary wire, we have, very nearly,

$$\frac{l_1}{4\sqrt{S}} = N_1 \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Therefore from (5) and (6)

$$\sqrt{S} = \frac{4\sqrt{2}\,E_1\,10^8}{p\,\mathbf{B}\,l_1} \quad . \quad . \quad . \quad . \quad . \quad (7)$$

This gives us the area of cross-section of the magnetic circuit.

For instance, for the transformer referred to above, we have $E_1 = 2{,}000$, $\mathbf{B} = 10{,}000$, $n = 70$, $p = 440$, and $l_1 = 30{,}000$.

$$\therefore \sqrt{S} = \frac{5{\cdot}66 \times 2000 \times 10^8}{440 \times 10000 \times 30000} = 9 \text{ centimetres nearly.}$$

Therefore, the magnetic circuit should have a cross-sectional area of 80 or 90 square centimetres.

To find the mean length of the magnetic circuit we must know the volume of the iron. This we can find at once if we know what total loss is to be allowed in the iron. For, supposing l to be the mean length of the magnetic circuit, then $S\,l$ is very nearly the volume of the iron, and if the total loss to be allowed in the iron is given and the maximum induction density, we can find the total volume of the iron which will permit this to be the case. It has been shown by Mr. Steinmetz (see *Electrician*, February 12, 19, and 26), that the iron core loss in a transformer can be calculated from the equation $W = \alpha n \mathbf{B}^{1\cdot6} + \beta n^2 \mathbf{B}^2$ when α and β are certain constants, and n is the frequency and **B** the maximum induction density in the core, and we can therefore calculate from the frequency, dimensions of iron bands, and the maximum induction density, the loss in watts per cubic centimetre in the core due to eddy currents and hysteresis. On applying this formula to real cases we find that the loss in laminated iron cores of the usual kind, worked at the usual induction densities, varies between one watt per 20 cubic centimetres of iron to one watt per 50 cubic centimetres of iron. This last is a liberal allowance. Hence, if we know the total loss in watts to be allowed in the transformer core and multiply this by 40 or 50, we shall have a good approximation to the volume of the iron necessary. If we take 50 cubic centimetres per watt we shall not be stinting the core of iron. In the present case, take 30 cubic centimetres per watt. In the case of the transformer con-

* These articles form part of Vol. II. of "The Alternate-Current Transformer in Theory and Practice." All rights reserved.

Digitized by Google

sidered, viz., a 22·4 unit one, we allowed 300 watts to be wasted in copper losses. Let 500 watts be decided upon as allowable for the iron losses. We have then to ask, what volume of iron will allow 0·033 watt to be wasted per cubic centimetre. Obviously,

$$\frac{500}{\cdot 033} = 15{,}000 \text{ cubic centimetres.}$$

Therefore, since the volume of the iron is $S\,l$,

$$S\,l = 15{,}000$$

and if S is taken as equal to about 90 square centimetres, we have

$$l = 166 \text{ centimetres nearly.}$$

Hence the mean length of the magnetic circuit must be 166 centimetres.

We can, therefore, draw the section of the iron core, or outline of the core plates. It will be as in the figure. The central web must have a width of 10 centimetres, and the other dimensions must be so arranged that, whilst the apertures in the plate (shaded portions) have a maximum area, the length round the dotted line is not more than say 150 centimetres. It is obvious that, whilst still maintaining the necessary length of magnetic circuit, it is possible to vary the relative magnitudes of the sides a and b of the rectangular holes. But since all the wire to be wound on the transformer has got to be wound through these holes, it will be often necessary to so choose a and b that we get the maximum size of aperture in area consistent with maintaining the magnetic circuit length constant,

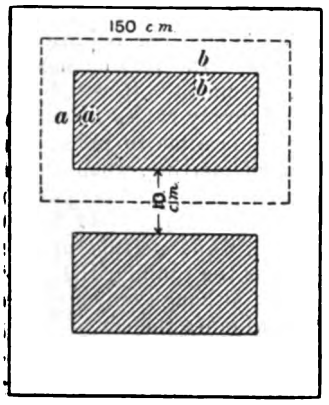

Diagram of Core Plate.

and to do this by making a equal to b. We have then finally to know the number of turns of wire in each circuit.

Roughly speaking, this will be equal to $\frac{l}{4\sqrt{S}}$, where l is the length of the wire and $\sqrt{S}$ is the length of the side of the section of the magnetic circuit. If l is equal to 30,000 centimetres, as above found for the transformer in question, this rule gives us $N_1 = 750$ as the approximate number of primary turns, and hence $N_2 = 37$ as the approximate number of secondary turns.

We have found, then, the length, size, resistance, and number of turns of each circuit, and the dimensions of the magnetic circuit.

We can then calculate the relative volumes of iron and copper. Taking the case in consideration, we find the total volume of copper to be 3,000 cubic centimetres, and that of the iron 14,300 cubic centimetres. A little consideration will show that, since the wire on the coils has all to be wound through the aperture in the core, the limitation to the diminution of the core, and therefore to the loss in the iron, is to be found in the necessity for having a certain sized hole to get the wire wound through. If we calculate the area of copper exposed on cutting through the whole of the coils by a dimetral cut in the case of the transformer considered, we shall find that it amounts to about 74 square centimetres, and even if we allow three times this area for insulation, there will still be abundance of room left in the aperture of 32 × 32 centimetres to get all the wire laid in. Hence in this case we could with advantage reduce the iron volume and waste less in the core. It would require further considerable discussion to show how the best dimensions of the core can be obtained. It may be pointed out, however, that the above rough sketch of a predetermination of the constants of a transformer shows that if we are given—

(1) The primary and secondary electromotive forces;

(2) The required output of the transformer;

(3) The amount or fraction of the energy so transformed to be wasted in the copper circuits;

(4) The amount of energy to be wasted in the iron circuit;

(5) The maximum induction density to be allowed;

(6) The frequency of the alternations; and thickness of core plates.

We can then calculate—

(1) The lengths, cross-sections, resistances, and number of turns of the primary and secondary circuits;

(2) The length and cross-section of the magnetic circuit;

(3) The waste in the transformer on open circuits;

(4) The approximate primary current on open secondary circuit.

(5) The "drop" in the secondary electromotive force as far as regards the loss in the copper of the secondary circuit.

The designer of a transformer has generally to steer a course between conflicting or opposing conditions of design. He may aim at obtaining some one definite result, or he may try to combine these different conditions so as to obtain the best all-round combination. He may design, for instance, for high efficiency at light loads, regardless of magnitude of magnetising current or of "drop;" or he may aim at a high maximum efficiency and small "secondary drop," and leave the all-day efficiency to take care of itself. Again, it is a distinct advantage in one way for the iron core of a transformer to get hot in working, because it blocks out eddy current loss by lowering the conductivity of the iron, but in another respect it may be very disastrous to the insulation for it so to do.

As far as regards minimising energy losses, the iron core should be run as hot and the copper as cool as possible, and an ideal transformer should therefore have the iron enclosed and the copper ventilated. In the smaller sizes of transformers the iron core losses will always be relatively greater than in larger ones. A transformer for 250 watts (5-light) can hardly be made to lose less than 20 watts in the core, but a 500-watt transformer can be made to lose not more than 25 watts, and a 2,000 watt not more than 45 watts. Hence, supposing that in each case the loss in the copper is 2 per cent., we shall find the full load efficiencies come out respectively 90, 95, and 95·7 per cent., larger sizes being similarly still more efficient.

With respect to magnetising current we have seen that for closed circuit transformers a large magnetising current means proportionate loss in the core. The magnetising current can be reduced by increasing the number of primary turns; but then the secondary turns, and hence the secondary ohmic drop, is likewise increased. The only way in which this last can be then also diminished is by increasing the section of the copper in the secondary circuit, and so again reducing the secondary resistance. This would involve, of course, an increase of cost. In the case of large sub-station transformers it may be worth while to incur this outlay to reduce the copper and iron losses to the lowest possible amount. These may be roughly taken at one watt per pound weight for the iron core, and between four and five watts per pound weight for the copper when the current density is taken at 1,500 amperes per square inch.

The best ratio of iron to copper loss can only be found by trial. Generally speaking, we may say that a high "all-day" efficiency cannot be obtained unless the iron losses are kept small. Hence some designers have sought for the solution of a high "all-day" efficiency by employing open iron circuit transformers. In so doing, however, they meet with another

Digitized by Google

difficulty, viz., that they then encounter a large magnetising current. It is true that this current is a current having a small power factor, or is a "wattless" current when in the transformer; but it is not "wattless" in the mains and armature circuits, and a large "magnetising current" means, therefore, an increased loss in transmission, and a lowered plant efficiency. Condensers in parallel with the transformer have then been proposed as a means of extricating the open-circuit transformer from this difficulty. It is pretty clear, however, that all dielectrics possess some hysteresis, and Mr. Steinmetz has shown (see *The Electrician*, April 8, p. 602) that this dielectric hysteresis increases as the square of the electromotive force. Hence, if this is the case, unless we can find a dielectric which will bear working at 1,000 or 2,000 volts with negligible hysteresis, it may happen that the energy loss is merely shifted from one place to the other, and that a closed iron circuit transformer with magnetic hysteresis and small magnetising current is as good or better than an open iron circuit transformer with large "wattless" magnetising current, *plus* a condenser having some dielectric hysteresis working with it. We may avoid Scylla but fall upon Charybdis. There is room for more investigation before these points are settled.

TRACTION.

BY E T. CARTER.

The forces which come into operation in starting and maintaining in motion any vehicle, such as a tramcar, are inertia, friction and weight. The condition of equilibrium at any instant, whether the car be starting, stopping, or moving at a uniform rate, is that the total effort exerted in the direction of motion is equal to the sum of the resistances due to these three causes. Inertia resistance is measured as the product of the mass set in motion into the acceleration, and is therefore only of the nature of a resistance during the time the motion is being increased. While the car has a uniform motion no effort is required to overcome the inertia; and when the car is slowing down the effect of inertia is directly an effort in the direction of motion, and not a resistance. Friction is a force that is always in the opposite direction to the motion, and is therefore a positive resistance, whether the car be starting, slowing down, or maintaining a constant speed. The effort required to overcome this force depends upon the nature of the road or track, the conditions of lubrication of the axleboxes, the speed, and to a certain extent upon the gradient. Windage—a form of friction—depends upon the relative direction and velocity of the wind and car, varying as the square of the component of its velocity along the track. For moderate speeds, such as are met with in tramway work, the variations of road or rail friction with the speed and gradient are usually neglected, the effort required to overcome this friction being nearly the same at all speeds and along all moderate gradients. The following are some of the values for the effort required to overcome the friction of the track alone, on different kinds of track :—

	lbs. per ton.
Granite pavement	17·41
Wood pavement	41·60
Well-worn macadam	44·48
New macadam	101·09
Tramway (clean, wet)	15·00
„ (ordinary)	25·00
„ (very dusty)	60·00

These figures are reliable for speeds not exceeding six miles an hour; for greater speeds a considerable addition must be made on account of windage, the actual amount of which will depend upon the shape and beam of the car, and on the square of the velocity.

Weight comes into action as a resistance in an ascending gradient, as an effort assisting motion in a descending gradient, and is of no account on a level track. The amount of effort required to overcome the weight on a gradient is equal to the product of the weight into the sine of the angle of the gradient.

Collecting these three forms of resistance into one mathematical form, we may write—

$$E = 70.W\alpha + f.W + 2{,}240\,W.\sin\phi.$$

Where E is the total effort required in lbs.,

W is the weight in tons,

α is the acceleration in feet and seconds,

f is the frictional resistance per ton,

$\sin\phi$ is the gradient, expressed as 1 in so many feet.

From this it will be seen that a considerably greater effort is required at starting than on any other part of the run, especially if the start is made on an up-gradient. Taking the case of an ordinary tram line, a car weighing 10 tons would require an effort of about 250lb. to run it at a constant speed of, say, six miles an hour; and this would represent a useful H.P. of about 4. But if this car is required to start from rest, attaining this speed in a space of 50ft., the average acceleration will be 0·8ft. per second, involving an effort of 810lb., and a useful power of nearly 6 H.P. It is probable that at the instant of starting from rest the effort will be double the average figure during the acceleration. This would amount to 1,620lb. for an instant; but the speed being very low there would be only a small H.P. usefully employed. The figures would be even greater than those given above if the case of a car starting on a gradient is considered.

In electric traction the motor H.P. or E H.P. required to run a car does not stand in any constant ratio to the useful H.P., because the motor is, at starting, required to exert a very large effort under conditions in which its efficiency is very low. If we assume, what is very nearly correct, that the effort exerted by the motor as a torque on the driving spindle is proportional to the current in the armature, then it is evident that in the above case the current during the time the car is getting up speed will be about 3¼ times that required to run the car at six miles an hour, while at the very moment of starting it will probably be 6½ times as much. It will be remembered that this current is fed off supply cables or rails at constant voltage, since it is quite impossible to reduce the voltage of the mains at the moment of starting, when there are several cars on the same conductors. So that the figures which represent relative current and effort also represent the relative H.P. supplied to the motor, *i.e.*, while getting up speed the average E.H.P. is about 3¼ times the running H.P., and the maximum E.H.P. is about 7 times, although only a very small fraction of this power is required to move the car.

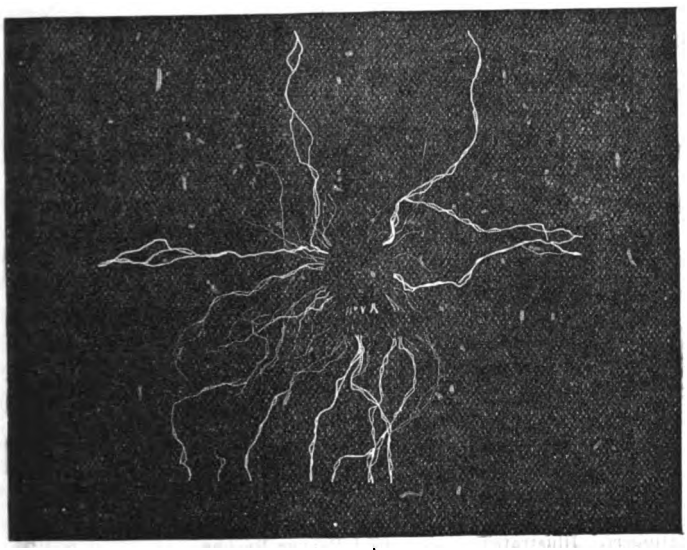
HIGH-PRESSURE DISCHARGES.

The accompanying illustration has been engraved from a photograph of a high-pressure discharge between two terminals separated by a glass plate, being one of the experiments shown by Messrs. Siemens Bros., at the Crystal Palace Exhibition. The current was produced by a Siemens' alternator, capable of giving a maximum output of 500 amperes, under a pressure of 80 volts. The alternator has 20 poles, and ran at a speed of 400 revolutions per minute, thus giving a frequency of 66⅔ complete periods per second. The current passed through the primary of a "cable" transformer, whereby the output was converted from 500 amperes × 80 volts to 15 amperes × 2,500 volts. The secondary of the "cable" transformer was joined by a concentric cable, about 200ft. long, to the primary of a triple-core transformer, the secondary of which gave ½ ampere × 50,000 volts. This is only one quarter of its total capacity, which is 2 amperes × 50,000 volts.

The glass sheets used were 2ft. square, and from ⅛th to $\frac{3}{16}$th-in. thick; the two brass disc electrodes were 3½in. in diameter, and were placed centrally on opposite sides of the sheet of glass and touching it; they were joined up directly to the secondary terminals of the transformer, and no spark gap was used, as in the experiments of Tesla, Elihu Thomson, and others. By regulating the exciting current of the field of the alternator the pressure was gradually raised from 20,000

Digitized by Google

volts to 40,000 volts or 45,000 volts. The photograph was taken at about 45,000 volts. From the experience gained from two months' work, it is possible to foretell that with a $\frac{3}{16}$th-in. sheet the brilliant flashes will occur at about 40,000 volts, while with a $\frac{1}{8}$th-in. sheet they may begin at 35,000 volts or even lower. An electro-dynamometer joined up in the circuit before the glass plate did not show any indication of a current passing, though $\frac{1}{10}$th ampere should have given a deflection of 25 divisions. Calculated from the current in the alternator circuit, which averages 100 amperes just before the sheet of glass is pierced, the current in the high-pressure circuit would not exceed $\frac{1}{10}$th ampere, and is probably very much less.



Discharge between two electrodes, 3½in. diameter, separated by a sheet of glass 2ft. square.

THE CULTIVATION AND COLLECTION OF GUTTA-PERCHA.

At a meeting of the Société d'Encouragement in April last, M. Sérullas gave a summary of the results of his latest expedition. The gutta-percha question is, in M. Sérullas' opinion, a serious one, and a grave crisis can only be avoided by methodical cultivation and thorough utilisation of existing resources.

The present mode of collection, he said, only made use at long intervals of mature trees. In May, 1888, M. Jungfleisch suggested to him that gutta-percha might be extracted from the leaves. The outcome of this suggestion was that leaves picked in Malay had been sent home to M. Jungfleisch and treated in the laboratory by an entirely new process, with results as decisive as they were unexpected. Not only did the extraction of the gutta-percha from the leaves prove extremely economical, but the yield was enormous, By this process every *isonandra* with leaves became *ipso facto* workable. One could obtain without touching the trunk a pure dried gutta-percha, amounting in weight to 8 to 9 per cent. of the raw material after the latter had been desiccated in a stove at 100° C. In future shrubs as well as decaying trees would be utilisable.

So long as the solution of this question was a process requiring a long time it was condemned to remain a Government one. Henceforth, an outlet was afforded for private enterprise. The plantations which might be undertaken and those which were being undertaken by Government would be workable after a short lapse of time; and until these were available French capital could make the utilisation of the last resources of the Malay forests the object of a vast undertaking, capable of procuring for it great and immediate profits.

Could a French Company procure in the heart of the savage regions of the Malay Peninsula raw material in sufficient quantity for immediate commercial and industrial operations? Undoubtedly! If they took no notice of the fantastic, but nevertheless truthful figures which had been published, and if they reduced as a flagrant exaggeration the figures relating to gutta-percha importations since 1843, and only considered undoubtedly genuine gums, they obtained the figure of decidedly more than one and a-half million for the number of their still existing vegetable progenitors. In the period of 48 years, from 1843 to 1891, the electrical industry alone had consumed more than 4,700,000 kg. of gums, which certainly came from the *isorandra percha*. By tapping the felled trunk an *isonandra* of from 12 to 15 years of age would only yield 90 to 110 grammes of impure moist gutta; it was impossible for a tree of 30 years to furnish more than from 250 to 260 grammes. At no period of its existence did the yield of a tree, under the native treatment, exceed 500 grammes. After having given this maximum the tree declined, and finally the exudation of the milk from incisions made in the trunk became next to nothing. In 48 years the same tree could only have been cut four times. Assuming that at the first cut every tree was at its best, it was evident that it could not have supplied by to-day more than 500+330=830 grammes of gutta. The production of 4,700,000 kg. therefore required the tapping of more than 5,600,000 separate trees. Local statistics and actual exports agreed with these figures, and pointed to the existence of more than one-third of these trees, say, at least, 1,850,000. These trees, it was true, had not long to live, and their exhaustion was beginning to render them for the most part of no good to the native. But if a vigorous adult tree was able to furnish without inconvenience every six months, and during a certain number of years, 1½ pecul* of dry leaves, the foliage of a tree already attacked by decay certainly did not weigh less than 1 pecul. A young tree of four or five years never had less than 2.9 to 3 kg. of leaves (weight taken after desiccation in a stove). The leaves of young trees and those of a recent growth were notably larger and somewhat richer in coagulated milk than the leaves of big trees. Moreover, the lopping of the branches, which were few at that period, considerably increased their number. It was very easy to make the *isonandra* grow in pollards. From a tree valueless to a native, that was to say too old to lend itself to trunk working, it was easy to gather leaves capable of yielding 4 kg. of gutta-percha. In one single day, and confining their operations to a tree of that description, they could extract five times as much gutta as the natives had succeeded in obtaining in half a century. A young tree of four or five years could by merely plucking all its leaves furnish a minimum of 261 grammes of gum; that was to say, just as much as a tree of thirty years was capable of giving when the trunk was sacrificed.

In short, there existed in the Malay forests more than 1,500,000 *isonandra percha*, soon to be lost for ever, and already beginning to be of no good to the natives, which contained within their organism more than 6,000,000 kilogrammes of gutta-percha. Assuming that the leaves which were picked were not replaced by fresh ones, there was here a more than satisfactory margin for a safe enterprise.

* 1 pecul = 62·5 kg. = 135·631lbs.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-NIGHT) FRIDAY, May 20th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Electro-Metallurgy." By J. Wilson Swan, M.A.

TUESDAY, May 24th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read: "The Measurement of High Temperatures." By Prof. W. C. Roberts-Austen, F.R.S. The last ballot for members for the session will be taken at this Meeting, which will be adjourned at 9.30 p.m., when the President and Council will hold a Reception in the Libraries.

SOCIETY OF ARTS.

8 p.m. Foreign and Colonial Section. Paper to be read: "The Extension of Colonial Trade." By Colonel Howard Vincent, M.P.

WEDNESDAY, May 25th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Researches in Photochromy." By F. E. Ives.

THURSDAY, May 26th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting.

FRIDAY, May 27th.

PHYSICAL SOCIETY.

5 p.m. Ordinary Meeting. Paper to be read: "On the Present State of our Knowledge of the Connection between Ether and Matter.—An Historical Summary." By Prof. O. J. Lodge, F.R.S.

OLD STUDENTS' ASSOCIATION.

7.30 p.m. Smoking Concert at Masons' Hall Tavern.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Emotional Expression." By Sir James Crichton-Brown, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*" *All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Phillippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday.*

MALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

ALTERNATE CURRENT DIFFICULTIES.

Alternating and continuous current supply are not yet on equal competing terms. The former is still handicapped by a mass of complications, and many an engineer declines to face the mathematical intricacies of the subject, excusing himself on the ground that high pressures are dangerous and unnecessary. The exponents of the alternate-current system have only themselves to thank for the present state of this branch of electrical engineering; some of them are rather fond of mysteries, and few have the power of expressing themselves in attractive language. If steam-engine construction had begun with thermodynamics, in the same way that alternate-current work has started on a strictly scientific basis, there would have been a general impression that without a thorough understanding of $p\,v^{1.1}$, no one should dare to use steam expansively; and without full knowledge of BOYLE'S law, hyperbolic logarithms, and absolute temperature, no one should pretend to measure steam consumption. Steam engine-builders began in happy ignorance of all these things, and in a less degree the same course was followed at first in alternate-current work. But the conditions were soon altered, and no two electrical engineers are to be found who can agree on the best way of measuring the power taken by a transformer, or who hold the same views about those various losses by hysteresis, eddy currents, magnetising currents, &c., which have no parallel in continuous-current work. And yet it appears that if any one can but hold up a theory, however

Digitized by Google

unintelligible, and stick to it, he thinks he has a right to rank among alternate-current workers; while the plain continuous-current man, who says that he is an amateur in all this, is regarded as of a lower order altogether, and if he uses an alternator and a few transformers for practical work, and does not pretend to an opinion on the relative merits of FOURIER'S theorem and exponential functions, he is in danger of being considered a spy.

One of the most complicated branches of the subject to a beginner is that of measuring the energy given out by a dynamo or absorbed by a transformer. Split dynamometers, triple voltmeters, triple ammeters, compensated wattmeters, electrostatic wattmeters, have their advocates and their opponents. If an attempt be made to measure the output of a dynamo, careful consideration must be given to the disposing of the waste energy; iron wire coils are treacherous, and a water tank is not above suspicion. The veriest tyro knows that he must not multiply volts and amperes together and expect to get the energy given out by a supply station; and yet, in reckoning up his efficiency, he has to take something more into consideration than the true energy supplied to the transformers as measured by split or triple instruments.

The continuous-current man reads off on a meter the output of his station, or figures it out with ease from the log sheet; he knows his fall of volts, and takes the indications of his pilot wires with confidence; all the amperes he sends out get through the lamps and so home again, unless bad leaks are tolerated. But no such easy lot falls to the alternate-current engineer. His volts are his first trouble; he cannot measure them direct on a CARDEW or magnetic voltmeter, for even hundredths of amperes are expensive at 2,000 volts. He is warned that he cannot depend on the ratio of transformation if he tries to "step down," and he waits before he orders an electrostatic voltmeter until someone else has used one, until he knows how it has been calibrated, and whether it will short circuit if he sneezes in the same room with it. At the worst, he can use his engine-room lamps as an indication. When he comes to measure his amperes, he is told that certain ammeters are only correct for a particular frequency, in fact they are only correct when they are correct, and at other times it is not safe to apply a correction as could be done to Capt. CUTTLE'S watch. When he has got his amperes he may not multiply them by his volts. He may choose between FERRARIS, BLAKESLEY, AYRTON and SUMPNER, FLEMING, and SWINBURNE, for a method of measuring the true energy delivered; but when he comes to consider his coal bill he finds that he is sending something else out of his station. The true watts are only what he gives to the transformers, and the wattmeters take no account of the lagging, spurious, or watt-less amperes. To find the C^2R losses he must measure the amperes independently, and knowing the resistance of the mains, add the loss to the energy delivered. No observations of this kind have yet been published, but then no coal bill of an alternate-current supply station has yet appeared on which it has been possible to base any deductions.

Considering how little HUME'S "plain man" or BERKELEY'S "thinking gentleman" can understand about alternating-current work, it is a marvel that it runs continuous currents so close. Only quite recently transformer men, after being taunted about heavy coal bills, suddenly admitted that the present system was wasteful and temporary, and that sub-stations will knock off 20 per cent. or so of present losses. We should not be surprised to see an almost unanimous change in favour of inductor dynamos, and an equally important revolution might be effected by the adoption of condensers for supply work. Alternating currents are occupying the attention of some of the best men, and great success is meeting their endeavours; but the mathematical jargon of the subject still repels many others equally good, and will continue to do so until a clear distinction has been made between lecture-room work and shop work in this particular branch.

OBITUARY.

EUGENE H. COWLES.

We regret to have to record the death of Mr. Eugene H. Cowles, who died at El Paso, Tex., on April 21st, at the early age of 38. Mr. E. H. Cowles had attained a world-wide recognition by the scientific world for his inventions in connection with the manufacture of aluminium. These inventions, in the origination and development of which he was assisted by his brother, Mr. Albert H. Cowles, involved in principle the application of the heating action of the electric current for the reduction of aluminium and other metals. Mr. Cowles was also connected in the engineering world with the invention of the trolley system.

Mr. Cowles, who was born in Cleveland, O., began his career as a reporter for the *Cleveland Leader*, of which his father was editor. After two years he, however, turned his attention to civil engineering, and very soon became interested in the production of aluminium. A small plant was erected at Cleveland, O., by the Cowles Brothers, where they invented the well-known Cowles process, out of which have grown the large aluminium works at Lockport, N.Y., and the Cowles Aluminium Company of the United States and Great Britain. The result of this invention was a revolution in the aluminium industry as profound as that caused by the earlier work of Deville. To carry out their process effectively, the Messrs. Cowles were compelled to do a large amount of pioneer workin connection with the design of dynamos of large power, the control of currents of hitherto unprecedented magnitude, the manufacture of carbon electrodes of great size, and to work out, in the face of many difficulties and discouragements, many details of operation that now seem comparatively easy, but for which at that time there were no precedents to build upon.

The first institution of learning to take note of, and to recognise the importance of the inventions of the Cowles Brothers, was the Franklin Institute, to the *Journal* of which we are indebted for most of these particulars. Shortly after the first public announcement of the Cowles process, an invitation was extended to the inventors to read a Paper on the subject before the Institute. This Paper was presented at the meeting held January 20, 1886, and, under the title, "The Production of Aluminium and its Alloys in the Electric Furnace," appeared in the *Journal* for February, 1886. It was an able and comprehensive treatment of the subject, and reflected the highest credit on its author. The success with which the efforts of the inventors to secure the general adoption of their process was crowned, sufficiently demonstrated that their faith in its commercial and technical value was neither misplaced nor exaggerated. The Franklin Institute, in recognition of the merits of the invention of the Cowles Brothers, awarded to them in 1886 the highest honour in its gift—the Elliott-Cresson medal—"for their invention of a new process in the metallurgical arts for the reduction of refractory substances," and recommended the award of the John Scott Legacy Medal and Premium to the inventors, "for their electric smelting furnace," which recommendation was subsequently confirmed by the Board of Directors of City Trusts. Subsequent events demonstrated that the judgment of the Institute in estimating the value of these inventions so highly was fully justified.

His untimely death, says "W. H. W.," in the *Journal* of the Franklin Institute, before he had yet reached the measure of years when those better equipped with physical endowments are in the prime of their powers for usefulness, is a loss which all friends of science will learn with sincere regret.

REVIEWS.

Prof. Hertz's Researches on the Propagation of Electric Force.
(Untersuchungen über die Ausbreitung der elektrischen Kraft. Dr. H. Hertz. Leipsic: J. A. Barth, 1892).

At some time or other every electrician has been questioned as to the nature of electricity, and has had to return an unsatisfactory answer. So the majority of us, even those almost entirely engaged with its practical applications, have endeavoured to read and understand the present-day theories of electricity, and more especially to make ourselves acquainted with experiments bearing upon them. This being the case, Prof. Hertz needs no further introduction. As an experimenter of the first rank his name is already familiar to English electricians, and all will be glad to learn that he has found time to edit the volume of his collected papers which is now before us. The book has been enriched by two very interesting chapters, the first giving an historical account of Prof. Hertz's work, while the various theories of electric phenomena are reviewed in the second one. The author has also included in the work a forgotten paper of von Bezold, written more than twenty years ago, in which some of his own results are anticipated. As these results were obtained in a manner quite different from that of Hertz, their truth is strikingly confirmed by the agreement of the two independent methods.

We learn from the introductory chapter that Prof. Hertz was first attracted to the subject of electric waves by von Helmholtz, who called his attention to a prize offered by the Berlin Academy for a research on an experimental relation between electrodynamic forces and the dielectric polarisation of insulators. Helmholtz and Feddersen had already investigated under what conditions the discharge of a Leyden jar might give rise to an oscillatory electric current, and Hertz hoped to extend their researches. He tells us, however, that at this stage he considered such electric motions far too irregular and violent to be made use of, and it was not until 1886, at Karlsruhe, that clear evidences of simple oscillations in metallic circuits were obtained. A more powerful effect was produced by oppositely charging two conductors separated by a wire containing a spark gap; these conductors on discharging into each other through the wire, gave rise to waves of fairly definite period which were propagated to a considerable distance. With this discovery Hertz began his remarkable series of researches by which he succeeded in establishing that these electrical motions do not merely directly affect bodies at a distance, but, on the contrary, are transmitted by some medium filling all space; that this medium has properties similar to those of the ether which transmits the vibrations of light; and, finally, that the velocity with which waves travel through the medium is equal to the velocity of light. He also showed that ultra-violet light can so influence a dielectric as to make the passage of sparks across it more easy. It requires no further evidence to enforce the conviction that electricity and light are manifestations of one and the same medium. Maxwell had previously arrived at the same conclusion from purely theoretical considerations, namely, by comparing the mathematical equations of the propagation of electric disturbances through a medium with the corresponding equations in the case of light. The quantity which in the electrical equations is the analogue of the velocity of light was experimentally found by several observers to have the same value as the latter, and hence Maxwell concluded that both classes of disturbance were transmitted by the same medium. Hertz thus established by experiment what Maxwell had indicated from theory, and we now know that the difference between an electric wave and a light wave is one of length alone.

It would be quite impossible within the limits of a review to give any adequate description of the methods used by the author in his researches. Fortunately this is rendered unnecessary by the translations of the more important of Prof. Hertz's Papers, which Mr. G. W. de Tunzelmann prepared for readers of this journal (vide *The Electrician*, Vol. XXI., p. 587, *et seq.*). Translations of other Papers included in the present volume will be found in *Nature*, Vol. XXXIX., 1888-89, and in the *Philosophical Magazine* for 1889. The work of von Bezold, however, although of extreme interest, does not appear to have been hitherto published in the form of an English translation. He allowed an electrical machine to send sparks to a knob connected to earth partly through the secondary wire of an induction, and partly by another bye-path containing two metallic points with variable lengths of wire between them. The points were parallel to each other, and faced a glass plate resting on tinfoil, this latter being connected to earth. On charging the points the electricity leaked from them to the surface of the glass, thus electrifying it, and on scattering a light powder over the glass figures were formed (Lichtenberg's figures), whose shape was quite different, according as the point was positively or negatively electrified. When the bye-path had its two points close together the figures were the same for each, but on inserting a sufficient length of wire between them the one gave a positive and the other a negative figure. In this way Herr von Bezold marked off the nodes and loops of the vibration sent along the bye-path and reflected at its far end, and he measured the wave length. In many respects the results are similar to those obtained later by Dr. Lodge in his experiments with lightning conductors.

In the chapter on electrical theories Prof. Hertz points out an apparent inconsistency in Maxwell's theory of dielectric polarisation, which leads to very confused notions concerning the nature of electric charge. The theories of action at a distance all assume electricity to be something analogous to matter, which can be added to or taken away from a conductor, and which exerts forces of attraction or repulsion. Maxwell, on the other hand, regards an electric charge as simply produced by the sudden change of polarisation at the boundaries of a dielectric. A charge is therefore looked upon not so much as a property of the conductor as of the boundary of the dielectric in which the conductor is placed. This idea is seen more clearly in the case of magnetism. An iron bar is supposed to consist of particles, each of which is a small magnet. On magnetising the bar these particles are polarised, and turn so that their north poles all point in the same direction. We then have along the length of the bar a chain of particles with a free north pole at one end and a free south pole at the other. In the intermediate portions a north always faces a south pole, so that there is no free magnetism except at the ends. In the same way, the particles of a polarised dielectric have opposite (*i.e.*, + and −) properties on their opposite faces. In the interior of the dielectric these destroy each other, but at the ends they give rise to the phenomenon of electric charge. The apparent inconsistency referred to arises from the fact that Maxwell seems to regard a charge from the point of view of the "action at a distance" theories, as soon as he ceases to be immediately concerned with questions involving the consideration of the surrounding medium; for instance, in the cases of current electricity and electro-chemistry. That the medium does play an important part is seen when we recollect that only the superficial parts of a cable are effective in transmitting power by alternating currents—a fact for the proof of which both Hertz and Lodge have devised several most instructive experiments.

We venture to hope that the greatest stumbling-block to the spread of a knowledge of Prof. Hertz's work will speedily be removed, and that a translation of the present volume of collected Papers will soon be forthcoming. J. L. Howard.

THE BRADFORD ELECTRICAL TRAMCAR.

According to the promise made a fortnight ago, we illustrate by the accompanying engraving, the under frame of the electrical tramcar at Bradford. The motors and gear have been constructed by Messrs. Easton and Anderson, of Erith. The body of the car was built by the Lancashire Waggon Company. The wheels are 28in. in diameter and have a 5ft. 10in. base on rails of 4ft. gauge. The restriction of the wheel base is always a great difficulty in electric traction; and when the cars are large enough to necessitate the use of bogies, the difficulties are increased rather than diminished, for the motors have still to be packed away between the pairs of wheels. The car at Bradford, which, as we have observed on a former occasion,

Digitized by Google

has to compete with steam and not with horses, is probably as large as is profitable to run, having seats for 36 passengers. This car, having been built to demonstrate the suitability of electric traction for the extremely difficult conditions which are to be found at Bradford, Mr. Holroyd Smith has done wisely in providing very ample power; and the result has proved that even on the steep hill and curve, and with an over-loaded car, he can easily run and even stop and start if needed.

Owing to the rather large motors and limited space, it has been found necessary to incline the shafts slightly, the arrangement recalling a former design of Mr. Holroyd Smith, in which a worm was provided at each end of the shaft, one working above and the other below the driving axles, thus neutralising the thrust. Ball bearings are provided for the thrust collars of the present arrangement, and contribute, no doubt, in reducing part of the friction, which has always been so great an objection to the use of worm gear. A fairly fine pitch is, of course, desirable on grounds of mechanical efficiency; but with such a gear the car would be immovable, unless under current. Mr. Reckenzaun has used a long-pitch screw to allow the car to be pushed, and to run down hill freely; and Mr. Holroyd Smith has given special attention to the details of the threads and the shape of the teeth. The worms in the present example have three threads of 4½in. pitch. The worm wheel has, therefore, a pitch of 1½in., and has 34 teeth. The ratio of the gear is 11 to 1. One of the worms is shown in the side elevation, Fig. 1. The gear is completely boxed in, and runs in oil.

The arrangement of two armatures between a single pair of magnets has been employed before for various purposes, and is called a "dual motor" by Mr. Holroyd Smith. The armatures are 12¼in. in diameter, and are 11in. long. We understand that with a test on a brake, the motors and gear gave the remarkably good combined efficiency of 65 per cent., considerably better than might have been expected from the worm gear alone. The weight of the under-frame, with the two dual motors, gearing, axles, wheels, brakes, &c., is 4½ tons. The total weight of the car with fittings is 6½ tons. The brakes, switches, trolley-rod mounting, and other details have been worked out with great ingenuity.

The object of using so many motors was to overcome the difficulty of starting, and to enable a powerful effort to be exerted when climbing the gradient. We alluded on a recent occasion to some of the different methods which have been employed for this purpose. The torque being proportional to the current only; current alone, and no volts, may be said to be needed at starting. When the motor begins to run it generates back-volts, and electrical pressure is then needed, but only in proportion to the speed. In accumulator traction the large current, as well as the reduced pressure, is easily secured by coupling the batteries in parallel sets; but with conductor lines as at Bradford no change can be made in the volts, unless by wasting them on resistances. The double set of dual motors is the reverse arrangement, achieving much the same end, but at considerable cost and increase of weight, together with some loss of efficiency. There are three ways of arranging the armatures, and these are shown in Fig. 2. A resistance switch is provided for turning on the current gradually, and for minor regulation of speed. The four armatures are used

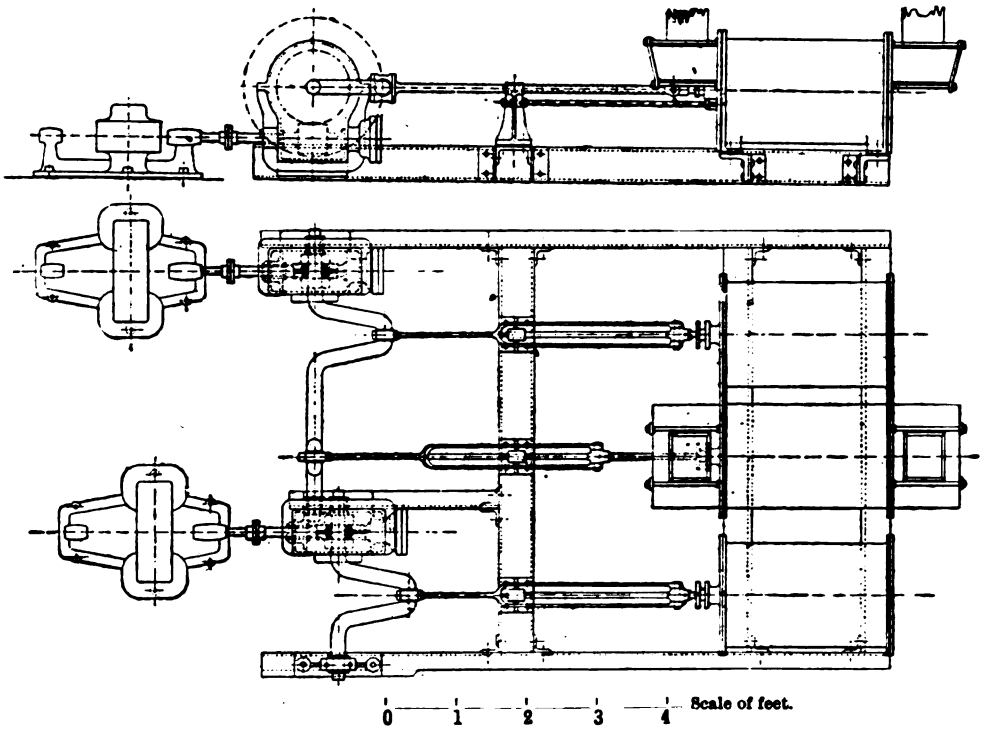
in series for ordinary running. To the dual arrangement Mr. Holroyd Smith applies the name "multiple parallel," which, unfortunately, conveys no meaning whatever to the uninitiated. This is used for heavy work or for occasional easy starting, and the complete parallel connection is reserved for the heaviest starting, being more than sufficient to run the loaded car up the 1 in 14½ gradient.

In order that the car may run freely round the curves, the wheels are not keyed together on the axles. Two wheels at opposite diagonal corners are keyed to the axles, the right-hand wheel at one end, and the left-hand wheel at the other being so fixed, and the worm wheels next to these wheels are also keyed direct to the axles. The other worm wheels are keyed to sleeves, which drive the remaining car wheels.

AN ELECTRICAL ORGAN-BLOWING APPARATUS.

The new organ erected in the large Concert Hall in the Goldsmiths' Institute, New Cross, containing 60 stops and 3,107 pipes, is blown by means of electricity, the apparatus having been designed and constructed by Messrs. Easton and Anderson, of Erith Iron Works.



Side elevation and plan of Electric Organ Blower.

The gear (*see* figure) consists of three cast-iron blowing cylinders, 17in. diameter and 24in. stroke, placed side by side on a framework made of rolled joists, secured to the concrete floor of the blowing chamber, which is situated at one end of the gymnasium. Two of these cylinders supply one regulating reservoir with wind at 5in. pressure, and the third cylinder supplies a second with wind at 10in. pressure, from which suitable trunks are led to the organ. The pistons of the two low-pressure cylinders are worked by a double-throw crankshaft, driven by a worm and worm-wheel, which is enclosed in a cast-iron casing, the worm being connected by a coupling with the spindle of the motor, which is capable of giving out ordinarily about 2½ H.P. The piston of the third cylinder is worked by a single-throw crank-shaft, with a similar worm gear and another motor of the same size. The motors always run at an approximately constant speed; and when the reservoirs are full, automatic bye-passes are opened between the ends of the cylinders, and the air is simply passed backwards and forwards until the reservoirs fall again and shut the bye-pass. Switches are arranged with suitable resistances close to the organ keyboard, by which either or both of the motors can be started, and which also provide a means of, to some extent, regulating the speed. The generating dynamo is driven by a countershaft and belts from the workshop shafting. It is capable of giving an output of about 100 volts and 50 amperes.

NOTES ON MR. W. H. PREECE'S PAPER ON "SPECIFICATIONS FOR INSULATED CABLES."*

BY C. HEIM.

It is stated in Mr. Preece's Paper on the above subject that it is frequently assumed that the insulation should be approximately proportional to the potential difference to be used, and that the exactness of the test increases with the rise of pressure. There follows then a number of values for the insulation resistance of a gutta-percha core, obtained from using different voltages between 14 volts and 560. The values obtained (in all cases after one minute's electrification) do not exhibit any effect due to an influence of the voltage on the insulation. Whilst the volts of the battery were being continually raised, the insulation resistance came out sometimes above and sometimes below the value it had with the lowest voltage.

For my own part, I venture to doubt whether it is practically the case, as Mr. Preece says, that the above assumption is generally made. In Germany, at any rate, it is not so. For instance, will any of my readers maintain that an insulation resistance measured with 50 volts will appear double as large as when 100 volts are used, or that a testing battery of 20 cells will show results only a quarter of those shown by a battery of 5 cells? If anything of this kind at all is generally accepted, it is only that an insulation resistance is found lower when measured with a high pressure than with a low one. Uppenborn was the first to give this fact his attention; Forderreuther and the present writer have proved by tests that there is a fall in the insulation resistance, measured by the ordinary substitution method, when the voltage is increased (see *The Electrician*, Vol. XXV., p. 751). It is hardly possible, so far as results at present obtained go, to give an exact law connecting insulation and voltage even for one material. The reason for this lies in the large number of sources of error which it is exceedingly difficult to eliminate.

* Abstract from the *Elektrotechnische Zeitschrift*.

Digitized by Google

Mr. Preece further considers it is sufficient for practical purposes to make use of the figures he gives. The figures, however, refer exclusively to gutta-percha. It would have to be regarded as an important step in the direction of progress if the non-existence of any of the possible variations in this substance could be relied upon. Unhappily, the tables are not provided with any details as to the influence of the two worst sources of error, viz., changes of temperature and the existence of residual charges. The values given for the insulation resistances at different voltages vary by as much as 7 per cent. It is out of the question to attribute such important differences to errors of observation, as for such resistances as those in question (from 100 to 200 megohms) there should not be any difficulty with proper testing arrangements in getting results within 1 per cent. of the true values. There remains, therefore, the possibility either that the temperature did not remain constant between successive measurements or that a sufficient interval of time for the residual charge to become dissipated was not allowed. In all probability both these causes have combined to produce the differences observed.

I have myself made the relation between insulation resistance and voltage, especially for gutta-percha, the subject of a careful examination. The greatest possible care was taken to maintain a constant temperature, and after each two minutes' electrification the copper core was earthed for a considerable time, depending upon the voltage used. Before taking each fresh measurement the existing residual charge was duly measured and allowed for, and every precaution was taken to secure reliability in the results. The conclusion arrived at was that a decrease in insulation resistance undoubtedly takes place when the voltage is raised. This decrease in the case of gutta-percha cables reached 6 6 per cent., whilst the voltage was raised from 50 to 460 volts in the case of electrifications lasting one minute, and 7·1 per cent. when they lasted two minutes. These results are the mean of eight different series of tests, in which the decrease fluctuated somewhat, though it was never under 5 per cent. Whilst the voltage was raised from 50 volts to 200, a decrease in insulation averaging 2 per cent. was observed. Two lead cables, the insulating materials in which were different, showed a similar decrease, though to a smaller extent than in the case of gutta-percha. The insulation resistances of two wires placed on the walls of a room and the field winding of a dynamo, fell off to a more noticeable extent.

From Mr. Preece's remarks, it would appear that he has remained in ignorance of my results although they were reproduced even in many foreign papers. (See *The Electrician*, Vol. XXV., p. 751.) I may add that whilst at the Frankfort Congress last year, Dr. Obach, of Messrs. Siemens Bros., informed me that measurements carried out by his firm on gutta-percha cores corroborated the results of my tests

NOTES ON THE LIGHT OF THE ELECTRIC ARC.

The following is an Abstract of the Discussion on the above Paper, which was read by Mr. A. P. Trotter on April 28th before the Institution of Electrical Engineers :—

DISCUSSION.

Abstracts marked thus (*) have been revised by the speakers.

THURSDAY, APRIL 28TH.

*Mr. SWINBURNE thought that the statement, due in the first place to Prof. S. P. Thompson, that the temperature of the arc was necessarily at that of volatilising carbon, gave us the means of constructing an electrical standard of light. What was wanted was a standard which was definite as to quantity and as to colour. Kirchhoff had shown that all incandescent bodies gave out light of the same colour, that is to say, having the same proportion of rays of different refrangibility. The amount of light given by each square inch at a given temperature depended on the emissivity. It was hardly likely that the emissivities of different kinds of arc carbons varied perceptibly. To get a standard, the image of the arc might be thrown on a screen by a lens, or preferably by a screen with a pinhole of known size. The image is thrown on the screen, the image of the crater being uniformly illuminated at a standard illumination of a standard colour. A second hole also of fixed area in a second screen is arranged in the middle of the image of the arc. Through this hole the standard quantity of light of the standard colour is transmitted. As Mr. Trotter pointed out, the colour of the arc light was practically that of daylight, and was thus the best for a standard. The quantity of light of any particular colour was thus also standardised. It was much to be regretted that Mr. Trotter had not given more information about arc lamps with alternating currents. With the same power it was to be expected that an alternating arc should give less light, as there were two small craters instead of one large one. In addition, one crater was on the wrong carbon. An ordinary alternating lamp also ran with less power, the pressure being lower. On the other hand, an alternating arc lamp was much easier to deal with, as an inductive circuit could be used to secure a steady light, instead of a wasteful resistance. He would like to hear the opinions of those who had had much experience of alternating arc lamps. He had tried passing a stream of gas through a hollow carbon in 1884 or 1885, but it did not increase the light at all ; it merely caused unsteadiness, or blew the arc out. There was a curious discrepancy between the light per square inch of the sun and of an arc. It could hardly be imagined that the sun could be blacker than carbon when cold.

Major-General FESTING, R.E., said that he firmly believed that the light from an electric arc lamp was real white light. He had observed that the arc light was distinctly yellower, but not to any great extent, than diffused daylight. After staying up all night, the sense of yellow light having become wearied, daylight appeared quite as ghastly as ever the electric light appeared to be. The idea of white was the integration of the whole light from the sun and sky. The blue light was not, strictly speaking, absorbed by the atmosphere, but was scattered. In matters of colour no absolute strict law could be laid down ; it could not be said absolutely that anything was white light.

*Dr. SUMPNER said that the explanation of the shape of the characteristic curve of the arc light practically proved that it was due to the fact that the incandescent surface of the carbon gave out light in any direction proportional to the apparent area of the surface seen from that direction. This was confirmed by a formula given at the Paris Exhibition in 1881, viz. :—The mean spherical candle-power was equal to half the horizontal candle-power, *plus* a quarter of the maximum candle-power. This could be explained by assuming that the characteristic curve was made up of two parts—the chief one being due to light emitted from the crater, considered as a bright horizontal disc, the other due to the more or less incandescent sides of the carbon.

*Mr. MORDEY said that he had never come across a uniform horizontal crater, he had always found them quite concave. It was stated that in the case of cored carbons the cored part was less brilliant than the rest of the crater, and he gathered that Mr. Trotter intended them to understand that the core was made of something other than carbon. He believed some makers now used certain substances not carbon ; but a good many carbons were made with simply soft graphite for cores, and in such carbons the arc was steadier, and there was no difference in the density, in the colour, in the degree of light over the crater. At the Naval Exhibition they had all admired the very large arc run on the lighthouse. It was visible over the whole of London, and seemed to burn very steadily whenever he saw it. That was an alternating current arc, and it certainly was steadier than any large direct current arc he had ever seen. In direct current search-lights they knew how difficult it was to get steadiness without a large steadying resistance in the circuit. With regard to alternating-current arcs, he entirely disagreed with the author of the Paper as to their being generally unsatisfactory and giving trouble. He had got better results with alternating currents than with direct and he put it down to the fact that first, they could use longer arcs with the same E.M.F. ; and the small difference of length, due to the feed, did not so affect the whole result of the arc as with the short direct current arc ; and secondly, to the fact that the alternating current caused a slight vibration in the mechanism of the lamp, and that assisted the feeding of the carbons. He quite agreed with Mr. Trotter's criticism of the lighthouse arc shown on the wall. He thought that was a very bad arc indeed ; the arc was far too short, the light could not get out. He thought there should be a length of clear arc, at least one quarter of the diameter of the carbons, to get good results. His company would have running a very large alternate-current arc lamp at the Crystal Palace Exhibition, taking about 200 amperes, automatically fed, and they would have the opportunity of seeing whether that lamp could be made as steady as an ordinary search light arc. He did not quite understand whether the arc could change its temperature during half a period of the generation of an alternating current. He thought that with any ordinary rate of alternation the mass of the carbon would be too great to allow of any fluctuation in temperature. It must surely act as a kind of thermal fly-wheel and have a fixed temperature during the whole period. With regard to the custom of the trade in calling a 10-ampere 50-volt lamp a 2,000 c.p. lamp, he thought they had high scientific authority. At the Paris Exhibition, or perhaps it was at the last Crystal Palace Exhibition in 1882, a committee containing, so far as he remembered, the President and several other scientific people, made some photometric measurements of the Brush arc lamp and brought it out at 2,300 c.p., and ever since then, as they had not altered the lamp, they had felt perfectly justified in describing it as a 2,000 c.p. lamp.

THURSDAY, MAY 12TH.

*Dr. FLEMING said : Mr. Trotter had mentioned the Saunderson method of introducing a hydro-carbon into the arc. He happened to have made a great many experiments with that arc lamp, and the results were interesting. Saunderson took for the bottom carbon a hollow carbon that had an asbestos wick up it instead of the usual soft core, and at the bottom of the carbon there was a metal vessel in which he placed some paraffin, vaseline, or easily fusible hydrocarbon, which was conducted by the asbestos wick up the bottom carbon, and then introduced into the arc. He made a good many experiments on the effect of introducing such vapours into the arc. The experiments were made with a photometer of the Bunsen type, having a special disc adapted for such purposes, and the standard of light was a 5 c.p. incandescent lamp, which was carefully standardised before and after the experiments against a Vernon-Harcourt standard lamp. The arc lamp used was a hand-regulated arc lamp ; he found that was the best method, as his assistant, with his hand on the slow-motion screw, and his eye on the voltmeter, could do better than any automatic mechanism. The experiments consisted in measuring the photometric intensity in various directions, first for a pair of ordinary carbons and then for a pair of the same sized carbons, in the same arc, only the bottom carbon was cored and had the vaseline led up it from the metal vessel. The size of the carbons was in all cases 13mm., and the lower carbon was either a good cored 13mm. carbon, or else an improved tubular

Digitized by Google

carbon supplied with paraffin oil. The results of these observations were then plotted down in the usual polar curve for the different angles. The red rays were excluded by a good ruby-red glass, tolerably monochromatic, and then also by a good signal green glass; and, taking the red rays first, it was found with the ordinary carbons they got the usual polar curve of certain dimensions, and on substituting for the bottom carbon the hollow Saunderson carbon with the paraffin in it; and drawing the same polar curve for the red rays, it lay outside the other altogether; there was not only more light in any direction but more light in all directions. A similar curve drawn for the green rays was found to lie outside the other, and the angle of greatest photometric intensity was somewhere about 30 or 40 degrees. Taking the intensity of the red ray for the ordinary carbon in the horizontal direction as unity, then the maximum red rays for the ordinary carbons in the direction of and 30deg. below the horizon was 3·44; the same rays in the improved carbon in the horizontal direction was 1·21, and in the direction of maximum intensity it was 4. The results were then converted into a figure, which Mr. Trotter said had no very definite meaning—the mean spherical candle-power; but the experiments showed that the mean spherical red light was improved 26 per cent., and the mean spherical green light was improved 24 or 25 per cent.; so that the introduction of this vapour into the arc had the effect of increasing that mean spherical candle-power in those ratios, and it was noticed that the introduction of this vapour into the arc greatly lengthened the arc. He found the arc about twice as long with the same voltage and currents when using the hollow carbons with oil, compared with its length with the ordinary carbons. Moreover, it was noticeable that there was certainly less cratering of the positive carbon when the prepared carbon was used. These results at the time were interesting, but he had not heard much since of this lamp in practice.

The table, given by Mr. Trotter, of light emitted per unit of surface from different sources was very interesting, showing the very wide range over which this luminous surface intensity extended for different sources of illumination. There was no mention in that table of a source of light which they might certainly have expected to find there, namely, an incandescent lamp. He could supply that figure which was missing. It came out very nearly identical with that of incandescent platinum. The surface intensity of illumination from melting platinum was given as 120 candles per square inch. The surface intensity of illumination of an incandescent carbon was about the same, viz., one-eighth of a candle per inch-mil. That was to say, if a unit of surface was taken whose length was an inch, whose shortest side was a thousandth of an inch, or a mil, and it was called an inch-mil, it was something at that rate. Mr. Trotter's figure in that table for an arc lamp, came out at 40 candles per inch mil. Therefore, comparing it with an incandescent lamp it was in the ratio of 40 to ⅛, or 320 to 1, a very striking difference indeed. One point of interest which ought to be decided—if it was possible to do so—by experiment was what ratio existed between those surface intensities and the true temperature of the surface; in other words, what function of the temperature of the surface was that surface intensity? It must be something like a cube or a fourth part. Dr. Fleming then described Rousseau's method of calculating mean spherical candle-power by rectangular co-ordinates.

Some time ago he commenced an investigation on a comparison between continuous and alternate-current arc lamps. He had an idea that there was an intrinsic inferiority in the alternate-current arc. He began by making a good arc lamp adapted for working either with an alternating current or with continuous currents, and determining the mean spherical candle-power of the arc taken from the polar curve, comparing that with the watts expended in the arc, and drawing a curve, or rather a series of curves, the horizontal distances being watts expended in the arc, and the vertical distances representing candle-power—that was done for different rays for the arc; for red rays and for a continuous current arc this watt candle-power curve was very nearly a straight line. He only stopped for want of better means of measuring the power taken up in an alternating arc.

Sir DAVID SALOMONS: Mr. Trotter started very early with these words: "A little consideration will show that the effect is precisely and identically the same as though the end of the positive carbon were flat." That was not strictly true. And afterwards he used all the arguments favourable to the surface of the carbon being cup-shaped, and therefore he arrived at the truth. If the positive carbon was flat the light issuing (omitting for a moment the refractive index) would gradually get less as the ray was more inclined, or less inclined, to this surface, so that if this carbon were really a flat surface it would be perfectly valueless for illuminating purposes, for the greatest quantity of light would be with the normal, and, therefore shielded by the negative carbon. But the fact of it being cup-shaped—they had a normal carbon, and therefore the light would be at a right angle from the source of light until they came to the line, when the carbon shielded it. If the carbon did burn flat, all the advantage got from the arc lamp would be gone, and it would be perfectly useless to attempt to use it until they made it burn cup-shaped.

Mr. R. W. WEEKES described a photometric apparatus, in which the light from an arc lamp in any direction was measured against the horizontal ray by means of mirrors.

*Mr. E. T. CARTER had been making some experiments since the Paper was read. According to the theory of heat they knew that the boiling point of a liquid depended upon the pressure which the liquid supported, and if the arc were placed in an atmosphere subjecting the vapour of the carbon to a higher pressure, the carbon would necessarily vapourise at a higher temperature. Consequently the surface of the carbon would be at a higher temperature, and there would be a higher efficiency, for the efficiency of any light source was a direct function of the temperature. He believed the temperature of the arc, as given by Sir William Siemens, was not 8,000° C., but 3,000° C. If it were assumed that the saturation curve of carbon vapour resembled somewhat the saturation curve of steam, then they could calculate approximately what the rise of temperature would be with a certain increase of pressure, and he had estimated if they subjected the arc to a pressure of eight atmospheres they would get a rise of temperature of the carbon of approximately 1,200 degrees; that was, more than the difference between the arc and glow lamp. The effect of this would be in accordance with the kinetic theory of heat. If the back E.M.F. was due to latent heat, as Dr. Thompson had clearly shown, a higher pressure would give a lower back E.M.F., and the minimum would be less than 39 volts. Mr. Carter then gave some calculations of the latent heat of carbon vapour.

*Prof. PERRY read a communication from Prof. SILVANUS P. THOMPSON, congratulating the author of the Paper upon the way in which he had straightened out the crooked problem of the distribution of light from the arc lamp. His intensely geometrical mode of viewing all matters had led him to discuss the arc lamp from a novel standpoint, and to give them the true solution of the problem. The starting point of Mr. Trotter's investigation was the recognition of the fact that the intrinsic brightness, per square millimetre, of the carbon surface of the crater was a fixed quantity. It also necessarily followed that the light emitted was always of precisely the same composition. He threw out the suggestion whether it was not worth while to reconsider the question of a standard of light, and adopt as a unit of light the light emitted by a square millimetre of crater. It was to be hoped that Mr. Trotter would be encouraged to complete his experiments on coloured shades, so as to give them a real daylight illumination. It was obvious that such shades could be used in conjunction with electric lamps, whether arc or incandescent, with far greater facility than with any flame lamps.

Mr. J. SHOOLBRED asked for the date of two communications published in *La Lumière Electrique*, one by M. Rousseau and the other by M. Palaz, containing some information with regard to polar curves. Some very interesting curves, the results of experiments carried out by MM. Sauttier-Lemonnier in Paris, were noticed; first, before the Society of Arts in 1878, and those and also some curves of alternate-current machines, taken from experiments carried out by M. Allard, of the French Lighthouse Department, afterwards appeared in a small publication in the year 1879.

*The PRESIDENT said that Mr. Mordey considered that he was justified in calling the light given off by a 10-ampere Brush lamp 2,000 and something candles, because the jury at the Crystal Palace in 1881 had reported that such was the efficiency of the Brush lamp. Mr. Mordey had coupled his name with that jury, and wished therefore to imply that the results were immaculate. However, he was not on that particular jury, and therefore was not responsible for the accuracy or inaccuracy of their results. Mr. Carter had assumed in his remarks that evening that the back E.M.F. in the arc was a perfectly definite and known number. He just wished to point out in passing that he was not aware of any tests whatever that had shown that there was a back E.M.F., still less that it had a value of 39 volts. Dr. Fleming's remarks with reference to the Saunderson lamp opened out a wide subject. The greater brightness probably was merely produced by greater length of the arc. The question of producing artificially, by means of arc or incandescent lamps, especially with arc lamps, lights of particular colours, was a subject which had interested him for some years past. On two occasions at the Royal Academy he had urged on Dr. Russell to bring the speaker's views before Sir Frederick Leighton, as to methods of arranging the pictures in the Royal Academy, and as to illuminating them with colour of a particular kind for a particular group of pictures. The question as to whether arc light was or was not blue with reference to white light was a subject which had been discussed backwards and forwards, and the advocates on each side considered that they were right. The explanation of that was that both were right. All depended upon what they meant by white light. They could easily prove that the arc was red compared with the sun by using what Mr. Trotter rather despised, red and green glasses. It was perfectly true, as he said, that they could not combine the results obtained with red and green glasses; they could not use the arithmetic mean, or the geometric mean, or the square root of the mean square; but he did not think that was any objection to making experiments with red and green glasses. In the same way they might speak about the experience of a person and the ability of a person, but they could not take the arithmetic mean, or the geometric mean, or the square root of the mean square of these two qualities; yet when judging of the value of a person they thought of his experience as compared with his ability. Arc lights were as a rule used not in the daytime but at night, and during the night white light was not sunlight. That brought them to the consideration of what was the definition of white light. He believed the proper definition was what they saw most of. Simply that. Up to the present time they had not seen most of arc lights during the evening, and so the standard of white light at night was gas light, and compared with that the arc was certainly blue.

*Mr. A. P. TROTTER apologised to the meeting for not being able to show the experiments which had been a second time promised. The terminals from the supply company had been there for ten days, but the insurance inspector had not been there. He had hoped to have shown one or two additional experiments with reference to what Mr. Swinburne said, and what Prof. Silvanus Thompson had also suggested, about using a portion of the crater as the unit of candle-power. Mr. Higgins had drawn his attention to the fact that the core of a cored carbon was distinctly less bright than the rest of the carbon—it was not such a good carbon for ordinary purposes, but had a valuable function in centring the arc. He suggested to Mr. Higgins to take a double carbon, one half as good as could be got, and the other a piece of battery carbon, and tie them together side by side, to see if one half of the crater was worse than the other. He had tried the experiment, but found that the soft carbon flared and flamed so much that it was difficult to make a test. This suggested that not only the emissivity but also the volatility of the carbon must be considered. The temperature must go down if the carbon was more volatile, and therefore he thought it could hardly be depended upon for a unit of light. The question had been raised about alternate-current arcs. He had had very

Digitized by Google

little experience indeed with alternate-current arcs, but was glad to hear Mr. Mordey had a high opinion of them, for that must mean that there was a great deal in them. The crater had been described as being a horizontal disc where it was really concave, and Sir David Salomons had given his views on the subject. He ventured to disagree altogether with them, but would not dwell upon the reasons. He could only repeat that no tilting of a luminous surface could make it brighter or less bright. Mr. Mordey had said that the alternating arc had time to get cool, and suggested that there was, as it were, a thermal fly-wheel, owing to the mass of carbon behind the crater, which would have enough heat to keep the arc going. If the crater were well focussed on a screen, and the current was reduced a little, the crater would suddenly curdle all over in a sort of flocks, and an instant afterwards the crater would diminish in size. He thought that as vapourising of the carbon took place at the surface and at the surface only, that the light also was given out by the surface alone where the truly white-heat carbon was really volatilised. An incandescent lamp carbon was different, the heat was all the way through the filament, and was in fact, greater in the interior.

Mr. Swinburne had pointed out a curious discrepancy between the light given by the sun per square inch and that given by carbon. A piece of the sun cut out and allowed to cool, ought to be 10 or 20 times blacker than carbon. But the pressure on the sun might be some tons per sq. in., and it was very possible that that might so raise the temperature, and thus account for it. He fully expected to have heard some remarks on some experiments made at the Standardising Institution with coloured shades. He understood that some experiments were made there with a screen, not blue, but grey, and with the Sun lamp, which was the Lampe Soleil resuscitated, and that some very good results had been obtained. Ayrton had given a very good reason for showing why they might use red and green glasses, and his analogue of ability and experience was most excellent. He said white light was what they got most of, but that was unfortunately not the case with ability and experience.

Dr. J. H. GLADSTONE then commenced the reading of a Paper by Mr. W. Hibbert and himself on "The Causes of the Changes of Electromotive Force in Secondary Batteries," but had not concluded when the time for adjournment arrived.

ON THE CAUSE OF THE CHANGES OF ELECTROMOTIVE FORCE IN SECONDARY BATTERIES.*

BY J. H. GLADSTONE, F.R.S., AND WALTER HIBBERT.

In 1882, Dr. Gladstone and the late Mr. Tribe sent to *Nature* four letters on the "Chemistry of Secondary Batteries." The main point established in these Papers was the all-important functions of sulphate of lead. They showed, in fact, that when a lead lead-peroxide cell is discharged, "sulphate of lead is the ultimate product on both plates;" and when it is charged again, "this lead sulphate is oxidated on the one plate, and reduced on the other."

In 1883, another letter appeared, in which, among other things, the effect of different strengths of acid when the cell is being charged was investigated, and the existence of occluded hydrogen, ozone, and hydrogen dioxide was considered.

These letters were subsequently published in book form.† In a Paper of the same authors in the *Journal* of the Chemical Society for 1883, p. 345, reference was made to the production of persulphuric acid in the electrolysis of oil of vitriol.

In 1883, Prof. Frankland‡ obtained substantially the same results, and proposed to ascertain the state of a cell during charge or discharge by observing the density of the acid.

In 1889, Messrs. Duncan and Wiegand§ investigated the rate of diffusion of the acid out of the pores of the spongy masses in the plates of a secondary battery.

In 1889, Heim‖ investigated the change in capacity of secondary batteries when used with different strengths of acid, and gave the E.M.F.'s observed when the strength varied from 10 to 35 per cent. H_2SO_4.

In 1890, we published experiments¶ which led us to regard the "abnormal initial E.M.F. of a secondary battery as due to inequality of acid strength, and its gradual disappearance as due to equalisation of strength produced by diffusion."

Shortly after this, an elaborate and valuable series of observations on accumulators was published by Messrs. Ayrton, Lamb, Smith, and Woods,** who have given curves showing the changes in potential difference under many conditions of working. They allude to our suggestion, and conclude on various grounds that it is insufficient to explain some of the phenomena.

In the discussion which followed this Paper, Mr. Hibbert urged that curves given by the authors afforded confirmation of our hypothesis.

Subsequently, two Papers were sent to the Royal Society by Mr. G. H. Robertson and Professor Armstrong,* of which only the abstracts have been printed. From these, as well as from a lecture by Mr. Robertson at the Society of Arts,† we gather that they attribute much to the formation of persulphuric acid and hydrogen dioxide.

We have lately been making additional experiments on the matter, which have led us to the conclusion that *variations in the strength of the sulphuric acid are the main cause of the variations in E.M.F.*

We propose to consider—

1st. What variations of strength of acid actually occur during charge, repose, and discharge.

2nd. Experimental determination of the change of E.M.F. produced by changing the strength of acid.

3rd. How far this is capable of explaining all that is known about the changes of E.M.F.

4th. Confirmations, experimental and theoretical.

5th. Other suggested causes.

PART I.—*What Variations of Strength of Acid actually occur during Charge, Repose, and Discharge.*

(*a*) *Changes during Charge.*—If we start with a properly formed cell which has been discharged, we have to deal with two leaden supports, on one of which there is a mixture of lead sulphate, $PbSO_4$, with more or less lead peroxide, PbO_2, and on the other a mixture of lead sulphate, $PbSO_4$, with more or less spongy metallic lead. Each of these mixtures is a porous layer the interstices of which may penetrate to the leaden support.

To avoid confusion, we propose describing the one as the PbO plate, and the other as the Pb plate.

If these be charged, the chemical action consists of the conversion of the lead sulphate on the one plate into PbO_2, and on the other into spongy lead, and the electrolytic change may be expressed thus:

$$PbSO_4 + H_2O \ldots . H_2O + PbSO_4 = PbO_2 + H_2SO_4 \ldots . H_2SO_4 + Pb.$$

It is evident that during this process sulphuric acid is formed in the pores of both plates, whilst at the same time an equivalent amount of water disappears.

Apart from this electro-chemical result which is equal on both sides, it is well known that during an electrolytic decomposition there is a gradual heaping up of the acid at what is now called the positive electrode, and a drawing of it away from the other. This increase of strength of acid at the peroxide plate may be seen by the descent of a denser layer of acid through the clear space under the plate. Indeed, it is well known that there is a circulation in the cell, the acid becoming stronger at the bottom and weaker at the top.

But to remove any doubt as to the strength of acid in the pores of the peroxide being greater than in those of the other plate, we made a direct experiment.

A cell was made of two small fully formed plates, each in a porous pot containing about 30 cubic centimetres of acid. These porous pots were placed in a large dish of the same acid and a current of 0·2 ampere sent through for two hours. After that time, the acid in the pot containing the PbO_2 plate had increased three per cent., whilst that round the Pb plate had diminished one per cent.

Of course, during the whole process of charging, diffusion is tending to equalise the strength of the acid, but it is much impeded by the capillary nature of the passages through which it must take place. It is quite conceivable that towards the end of charging, a film of the strongest acid—that is, H_2SO_4 itself—covers the working surface of the PbO_2 plate.

All these actions account for the well-known fact that during the charge the whole body of the liquid in a working cell rises in density by somewhere about 0·04.

(*b*.) *Changes on Repose.*—At the end of charging, the PbO_2 plate consists of porous peroxide attached to the lead support, surrounded by strong sulphuric acid. This sulphuric acid will diffuse out into the intermediate liquid at a rate which Messrs. Duncan and Wiegand's results show to be rapid at first. Complete equalisation is, however, a very slow process, to be reckoned by hours rather than by minutes.

But there are other actions reducing the sulphuric acid in the pores at the same time. The PbO_2 and its supporting lead are in a condition to set up energetic local action with the formation of sulphate of lead, and consequent absorption of sulphuric acid from the liquid. The chemical change is as follows:—

$$PbO_2 + H_2SO_4 \ldots\ldots H_2SO_4 + Pb = PbSO_4 + H_2O \ldots\ldots H_2O + PbSO_4.$$

(It must be remembered that the Pb in this equation is the lead support for the peroxide. Common experience shows that it is corroded during use.)

Digitized by Google

This action clearly will absorb sulphuric acid from the liquid in the pores and replace it by water.

In a well-charged plate, there is always at first an evolution of a little oxygen gas, which has been attributed* to the reaction of hydrogen dioxide on peroxide of lead.

$$PbO_2 + H_2O_2 = PbO + H_2O + O_2.$$

If this be the case, the oxide of lead (PbO) formed must also abstract its equivalent of sulphuric acid from the liquid.

Of the three causes of weakening—diffusion, local action, and reduction by H_2O_2—the first goes on till the acid in the pores is brought down to the same strength as that in the intermediate liquid. But the local action may still continue for many days and will tend to keep the acid in the pores a little weaker than that in the external liquid, notwithstanding the return diffusion of acid towards the plate.

Turning now to the Pb plate in repose, we find none of the above actions taking place, except the slow equalisation of strength produced by diffusion.

But there is an action peculiar to this plate—that is, a direct slow chemical action of the sulphuric acid on the lead, producing lead sulphate and hydrogen gas.† The equation is—

$$Pb + H_2SO_4 = PbSO_4 + H_2.$$

This must gradually produce a weakening of the acid in the pores, and it is important to notice that diffusion, which is always slow, will be almost entirely prevented by the choking up of the capillary passages by the gas evolved.

We have indicated the probability that towards the end of a charge there is a film of the strongest acid against the working surface of the PbO_2 plate. If this be true, it is evident that as soon as repose begins, such a film will almost immediately disappear, owing to diffusion into adjacent liquid, whether in the pores or out of them.

(*c.*) *Changes during Discharge.*—As soon as the discharge begins, a still more rapid reduction of the strength of acid may be expected. Diffusion, local action, and reduction by H_2O_2 will still take place on the PbO_2 plate, and the direct chemical action on the Pb plate, but on each plate there is superadded the ordinary discharge reaction of the cell. The form of the equation for discharge is the same as that already given for local action, namely—

$$PbO_2 + H_2SO_4 \ldots . H_2SO_4 + Pb = PbSO_4 + H_2O \ldots . H_2O + PbSO_4$$

(In this case the Pb represents spongy lead on the Pb plate.)

But while the absorption of sulphuric acid and production of water thus goes on in both plates, electrical transference of the H_2SO_4 now takes place from the PbO_2 to the Pb plate, causing an additional weakening of the acid in the pores of the first.

If discharge has commenced immediately upon the cessation of charging, these different causes will combine to produce a very rapid decrease in the strength of the acid at the PbO_2 plate.

In any case, a period must soon arise in which the great excess of sulphuric acid originally about the PbO_2 plate has disappeared through these various agencies, and the acid on both plates will be reduced to pretty nearly the same strength as that of the intermediate liquid. After this, there will be a gradual withdrawal of acid from the liquid in the pores, more or less compensated by diffusion inwards from the intermediate liquid. This, of course, brings about the reduction in the strength of the whole acid, which is well known to take place during discharge.

The strength of the acid in the pores will be determined by the relative values of the rate of withdrawal and the rate of diffusion. But while the rate of withdrawal continues constant for a given discharge current, the rate of diffusion rapidly diminishes.‡ The rate of weakening of the acid is, therefore, a constantly increasing one, and may finally become so rapid that the acid strength of the liquid against the working surfaces of the plates is very low or almost *nil*.

In such a case we may expect the formation of the white compound described by Gladstone and Tribe,§ which, when analysed, seemed to be a basic compound of the composition $2PbSO_4 . PbO$.

(*d.*) *Changes on Repose after Prolonged Discharge.*—If through prolonged discharge the acid against the working surfaces has become very weak, and the discharge is then stopped, it is evident that the acid in the pores will quickly increase in density, and uniformity of strength in and outside the pores will be restored after a while; but the general strength will always be lower than the original value. A renewal of the discharge will, however, soon lead to exhaustion of the acid against the working surfaces.

† Gladstone and Hibbert, *Phil. Mag.*, 1890, p. 164; Ayrton and others, *Jour.* Inst. Elec. Engineers, 1890, p. 680.

‡ This might be expected from the partial clogging of the pores by the $PbSO_4$ formed on both plates, and it has been experimentally shown to be the case by Messrs. Duncan and Wiegand.

§ "Chem. of Sec. Batts.," p. 46.

PART II.—*Experimental Determination of the Change of Electromotive Force produced by Changing the Strength of Acid.*

It is a matter of general knowledge that the E.M.F. of an accumulator rises slightly when the strength of the acid is increased. Incidental determinations of the rise occur in several Papers, of which we may mention one by Preece* and another by Heim.†

In 1890, thinking it probable that the chief cause of the high E.M.F. was "the great inequality in strength of acid produced by the charging current," we made some experiments which were described, with tabulated results, before the Physical Society.§ Instead of repeating these, we now throw the results into a diagram of curves (Fig. 1).

For each case, the ordinates represent E.M.F. of the cell in volts, the abscissæ represent time in minutes. The figures attached to the curves show the percentage strength of the acid round the PbO_2 plate. The Pb plate was always in 18·5 per cent. acid.

The curves show—first, that in each experiment the E.M.F. at the commencement of discharge is about the same value, 2·58 or 2·6.

Secondly, that the fall after stopping the charging current was initially more rapid in the case of the weaker acid. The subsequent and more permanent E.M.F. also depends on the strength of the acid, the value for 58 per cent. acid being 2·27 volts; for 34 per cent. acid, about 2·15 volts; for 18·5 per cent. acid, about 2·01 volts. When the cell has been in repose 15 minutes, the weakest acid gave 0·26 volt less than the strongest, and 0·14 volt less than the 34 per cent. acid.

Thirdly, that if, when the E.M.F. has fallen, the strength of the acid be increased, the E.M.F. quickly rises, and, as the acid soaks into the pores, eventually attains about the same value as if that particular strength of acid had been maintained throughout.

This seemed to justify our conclusion, but we were desirous of obtaining more direct evidence of the effect of varying strength of acid. In our old experiments we measured E.M.F. by the condenser method, and have again found it useful in many experiments. But we have now made more accurate determinations by the potentiometer, and in one series of experiments by observing the current obtained through a high resistance.

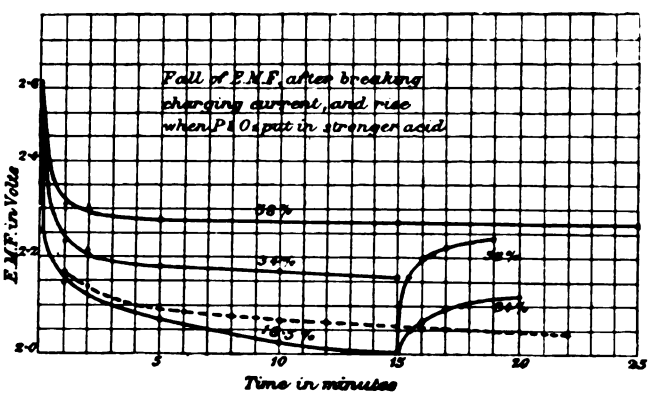

FIG. 1.

Throughout the new experiments we have employed the same two plates. The supports consisted of thick lead wire doubled on itself. These were pasted with red lead and then "formed" in the usual way, until the paste on one was pure lead, and on the other pure peroxide of lead. The active part of each was about 3in. long and half an inch diameter. The containing vessel and acid varied according to requirement, as described below for the particular experiments.

We found that on transferring the plates from a weaker to a stronger acid the E.M.F. begins to go up, at first rapidly, afterwards more and more slowly. But the final value is not reached for some hours. It was impossible to allow so much time for each observation, and in our earlier experiments we made our determination of E.M.F. at the end of twenty minutes or so. Consequently in these our figures do not represent the ultimate value of the E.M.F. for that strength of acid, but they do not fall much short of it.

In all experiments the plates were fully charged, and before being used were washed free from the liquid products of electrolysis.

First Series.

In the first series both plates were immersed in acids of the same strength. When one observation had been made, the plates were quickly transferred to another cell containing stronger acid, and the E.M.F. occasionally tested for fifteen minutes, when it was

* *Proc.* Roy. Soc., 1883, p. 460. § *El. Zeit.*, 1889, p. 88.

† *Phil. Mag.*, 1890, p. 168.

Digitized by Google

finally observed, and the plates again removed into a cell containing still stronger acid, and so on. The following table gives the results :—

Table I.

Acid in cell round both plates.		E.M.F. of cell in volts.
Density.	Percentage strength.	
1·045	6·5	1·887
1·065	9·5	1·898
1·080	11·5	1·915
1·115	16·2	1·943
1·157	21·7	1·978
1·217	29·2	2·048
1·254	33·7	2·088
1·335	43·0	2·170

The last acid was found to act vigorously on the spongy lead, so that this series was discontinued.

Second Series.

The same procedure was followed, with the exception that the Pb plate was kept throughout in acid of density 1·098 = 14 per cent. The peroxide was transferred from one to another of a series of porous pots filled with acids of the strength given below :—

Table II.

Acid round PbO_2 Plate.		E.M.F. in volts.
Density.	Percentage strength.	
1·045	6·5	1·926
1·065	9·5	1·932
1·080	11·5	1·939
1·115	16·2	1·949
1·157	21·7	1·963
1·217	29·2	1·986
1·254	33·7	2·013
1·335	43·0	2·061
1·53*	63·0	2·22
1·75*	81·0	2·33

The results of the two series are plotted in the following diagram (Fig. 2) :—

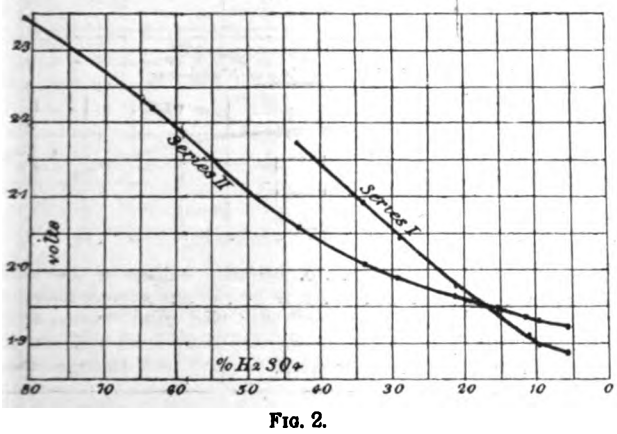

FIG. 2.

It will be seen—first, that in both cases the E.M.F. increases with the strength of the acid, although in Curve II. there is no change in the acid at the Pb plate ; secondly, there is no coincidence of the curves except where the conditions of the experiments are practically identical ; thirdly, that for any given abscissa the E.M.F. in Curve I. is smaller than that in Curve II. when the acid about the Pb plate is less than 14 per cent., and greater when it is more. Hence it follows that the E.M.F. depends on the strength of the acid at both electrodes.

Third Series.

Not being satisfied with the range or the accuracy of the preceding series, we endeavoured to obtain a curve representing the relation between E.M.F. and strength of acid within the widest limits.

After preliminary trials and considerations, we adopted the following plan. The experiments were divided into two parts, in consequence of the action of strong acid on spongy lead.

* The two last observations really belong to another set of experiments, where the acid round the lead = 23 per cent.

In the first part, we commenced with an acid of 5·6 per cent., and worked upwards to 49 per cent., allowing the plates to stand half an hour in each acid before final observation of E.M.F. The process was then reversed, working downwards through the same acids to 5·6 per cent. again, and then continued through weaker acids to a mere trace—less than 0·05 per cent.—and the cycle finished by returning once more to 5·6 per cent. As even half an hour or an hour is scarcely sufficient for equalisation of the strength of the acid within and without the pores of the plates, it may be expected that the ascending series would scarcely represent the full effect of the rise, whilst the descending series would scarcely represent the full effect of the fall. We therefore give in Table III., not only the numbers actually obtained, but also the means of the ascending and descending series, which cannot be far from the true values. We have proof of this in the case of the 5·6 per cent. acid, where the mean is 1·89 volts, while the true E.M.F., as very carefully determined previously for the same strength, was 1·88 volts. This agreement also proves that no appreciable change had come over the plates during the operations.

Table III.

Time of soaking.	Density of acid.	Per cent. H_2SO_4.	E.M.F. in volts.		
			Ascending.	Descending	Mean.
1 hour	...	Trace	...	1·507	1·507
,,	1·008	1·2	1·747	1·777	1·762
,,	1·013	2·0	1·792	1·825	1·808
,,	1·020	3·1	1·835	1·867	1·851
,,	1·037	5·6	1·875	1·908	1·891
30 minutes	1·071	10·4	1·922	1·953	1·937
,,	1·154	21·3	1·993	2·016	2·004
,,	1·233	31·2	2·055	2·066	2·060
15 ,,	1·388	49·0	2·149	...	2·149

In the second part of the experiments of this series the Pb plate stood throughout in 27 per cent. acid. We commenced with the PbO_2 plate in 43·5 per cent. acid, ascended to 88·5 per cent., and then returned to 43·5 again. A longer time was here allowed for diffusion, as the strong acid is very viscid. Notwithstanding this longer soaking, the differences between the ascending and descending series are greater than before. The results are given in the following table :—

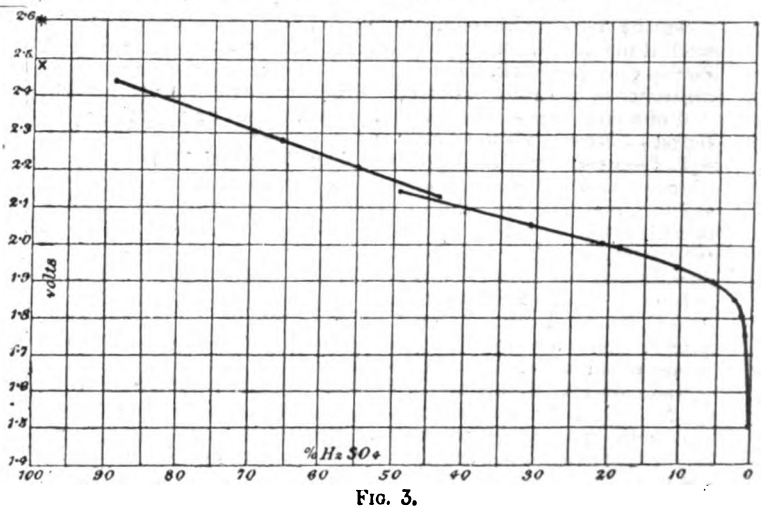

FIG. 3.

Table IV.

Time of soaking peroxide plate.	Acid round peroxide.		E.M.F.		
	Density.	% H_2SO_4.	Ascending.	Descending	Mean.
50 minutes	1·338	43·5	2·106	2·163	2·135
50 ,,	1·446	54·8	2·179	2·233	2·206
50 ,,	1·569	66·0	2·259	2·298	2·277
60 ,,	1·605	69·0	2·279	2·342	2·310
60 ,,	1·723	79·0	2·354	2·398	2·376
60 ,,	1·814	88·5	2·442	...	2·442

The mean results of Tables III. and IV. are given in the above diagram (Fig. 3) :—

The two curves very nearly join, and when it is considered that the highest E.M.F. of the lower curve is almost certainly too low,

Digitized by Google

and the lowest E.M.F. of the upper curve too high, the coincidence it striking.

An attempt was made to get an observation in very strong acid. The fully charged PbO_2 plate was washed in water, and dried at 100° C. It was then soaked in 95 per cent. acid. After 34 minutes' soaking the E.M.F. was observed, and the plate then placed in weaker acid. In consequence of absorption of water from the adjacent liquid of the cell, as well as from the atmosphere, the acid round the PbO_2 plate fell from 91·5 per cent., the Pb plate standing all through in 27·5 per cent. acid. Results are given below, and are fairly confirmatory of the previous figures :—

Table V.

Time of soaking.	Acid round PbO_2 plate.	E.M.F.
34 minutes	91·5 %	2·44
53 "	77·5 %	2·37
67 "	65·5 %	2·28
97 "	53·0 %	2·16

The highest E.M.F. here obtained (2·44) is very nearly the same as that given in Table IV. for 88 per cent. acid.

A still further effort was made to get an observation in the strongest acid. A PbO_2 plate was soaked all night in 80 per cent. acid, and in the morning transferred to a jar containing 99 per cent. H_2SO_4. This was kept under a closed bell jar for four hours, after which the E.M.F. between the PbO_2 in this strong acid and a Pb plate in 25 per cent. acid was measured by potentiometer. The value was 2·47 volts, which, after 30 minutes' further standing, rose to 2·48 volts nearly. This is represented in Fig. 3 by the small cross ×.

It was expected that a still higher voltage could be obtained if both plates were immersed in the strongest acid, undiluted H_2SO_4. The difficulty was that this acid acts pretty readily on the spongy coating of the ordinary Pb plate, so we made an experiment with a strip of ordinary clean sheet lead. Placing this in the same H_2SO_4 in which the PbO_2 plate had been standing for some hours, the E.M.F. was found to be as high as 2,607 * volts. This is indicated in Fig. 3 by an asterisk (*).

PART III.—*How far are these Results capable of explaining all that is known about Changes of E.M.F.*

At the very beginning, it is evident that the experiments described in Part II. more than cover the range of variation in E.M.F. during ordinary work. For these limits are : a maximum potential difference of 2·5 volts at the end of a charge, and 1·8 volts at the end of a discharge—figures which come within the variations produced by strong and weak acid.

But our results go much farther than this ; and for the purpose of detailed consideration we shall compare them (as shown in Parts I. and II.) with the valuable observations of Prof. Ayrton and his collaborateurs. Their Papers in the *Journal* of the Institute† contain the most elaborate and trustworthy account of working variations of potential difference which has yet been published.

In order to make the comparison more evident to the reader, we give the two time curves (Figs. 4 and 5) of E.M.F. in charge and discharge. They are deduced from the curves of potential difference values given by Prof. Ayrton and others in the figures opposite p. 661, by making allowance for the resistance as exhibited on pp. 590 and 592. We indicate for certain marked points in the curves the percentage strength of the acid in the general body of the cell as deduced from the specific gravities given on pp. 672 and 673.

As far as charging is concerned, we have already shown that sulphuric acid must be continuously formed by the decomposition of the sulphate on each plate, and that the acid must become more and more concentrated, especially against the PbO_2 plate. If our views be correct, this must give rise to an immediate rapid increase of E.M.F. ; but as the action proceeds, the tendency of the heavy acid to sink towards the bottom of the vessel, or to diffuse into the weaker intermediate acid, will become greater, and a point will be reached when the production of sulphuric acid against the plate will be nearly counterbalanced by its dispersal. The E.M.F. will still rise slowly, because the intermediate acid is gradually increasing in strength.

This evidently is the tale that is told by Fig. 4. Beginning with an external acid of 24·6 per cent. and a corresponding E.M.F. of about 2·03 volts, there is a rapid rise—so rapid, indeed, that by the end of half an hour the E.M.F. has become 2·1 (which is about equal to what would be given by a 40 per cent. acid at each plate—*see* Fig. 3), whilst the intermediate acid has not risen, but is only 24·5 per cent. The increase of E.M.F. due to increase of strength of acid against the plates then becomes very slow ; but after about nine hours it is found to have risen to what we may look upon as 45 per cent. or more against the PbO_2 plate, while the intermediate acid in the cell has risen to 27 per cent. It subsequently rises against the working surfaces of the plates to 55, and eventually to at least 66 per cent., or probably much more, though the strength is little increased in the body of the cell.

When discharge commences we have shown that there must be a very rapid weakening of the acid from diffusion and formation of lead sulphate till the losses are fully counterbalanced from the intermediate acid. There will then be no material reduction till the intermediate acid is considerably reduced or prevented diffusing freely into the pores of the plates. This is the explanation of Fig. 5. We see the rapid fall of E.M.F., the bulk of which takes place in the first few minutes (*see* Ayrton and others, pp. 545 and 546, and our experiments, Fig. 1). After about half an hour the E.M.F. is reduced to about 2·03 volts, indicating about 25 per cent. H_2SO_4 against the plates, while the intermediate acid is 27·8 per cent. This state of things lasts for some hours, but the absorption of the free acid that is in the pores of the plates gradually reduces the strength there below that of the intermediate liquid, so that after eight hours the internal acid is about 22 per cent., while the external strength has sunk only to about 26 per cent. The acid against the plates then declines more rapidly, so that in four hours more the E.M.F. is equal to that which would be given by 7 per cent. at each plate, while the intermediate acid has scarcely sunk below 25 per cent.

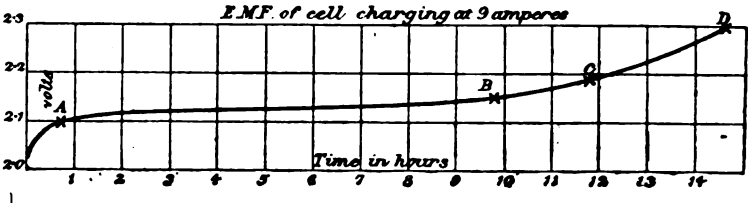

FIG. 4.

Acid in General Body of Cell during Charge.

At point.	Density given.	% H_2SO_4.
A	1·178	24·5
B	1·198	27·0
C	1·201	27·4
D	1·206	28·0

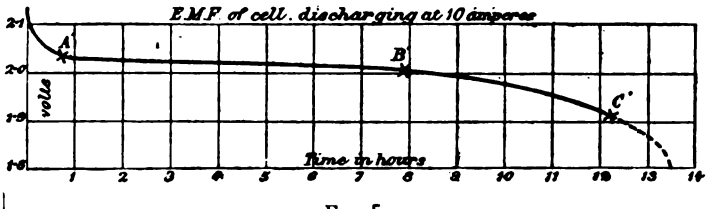

FIG. 5.

Acid in General Body of Cell during Discharge.

At point.	Density given.	% H_2SO_4.
A'	1·205	27·8
B'	1·189	25·9
C'	1·180	24·8

We have already mentioned in Section I. that when the acid is very weak the compound $2PbSO_4.PbO$ may begin to form. Should this be the case, the acid absorbed per ampere-hour would be less than before by about one-third. This is about what was found by Dr. Frankland, and described by him in the discussion on the Paper by Prof. Ayrton and his colleagues (*Jour.* Inst., XIX., 698). Dr. Frankland shows that in some prolonged discharges there was some such reduction of the absorbed acid, and that the diminished rate of absorption began when the voltage fell below 1·8—a figure indicative, on our hypothesis, of a weak acid in the pores of the plates.

We have also shown that if through prolonged discharge the acid in the pores has become very weak, a stoppage of the discharge ought soon to bring up the acid towards what it is outside. The E.M.F. ought therefore quickly to increase to the normal, or nearly so. This rise after rest was observed in very early days, and has been frequently discussed, as, for example, by Messrs. Gladstone and Tribe ("Chem. Secondary Batts.," p. 28), and by Prof. Ayrton and other.

* The same E.M.F. was obtained whether the lead was cleaned by scraping with a knife, or by washing with acetic acid.

† *Loc. cit.*, pp. 661, 545.

Digitized by Google

We have already seen that if a charged cell be allowed to rest without discharge, the acid in the interstices of the Pb plate is slowly weakened by its action on the lead with the evolution of hydrogen gas. The gas will tend to clog the interstices and impede the stronger acid outside from diffusing inwards.* The lower strength of internal acid will produce a lower E.M.F. than would be obtained if the internal acid were of the same strength as the external. In other words, a discharge after long repose ought to commence with a somewhat low E.M.F. But one effect of discharging will be to remove the impediment to free diffusion produced by the enclosed gas, and thus tend to increase the strength of the internal acid, with a consequent small rise in E.M.F. as the discharge goes on.

Now Prof. Ayrton and his colleagues obtained these very results in two instances. The curves representing one of these we have reproduced (Fig. 6) from their Paper, with two previous normal curves, *a* and *b*, for comparison.

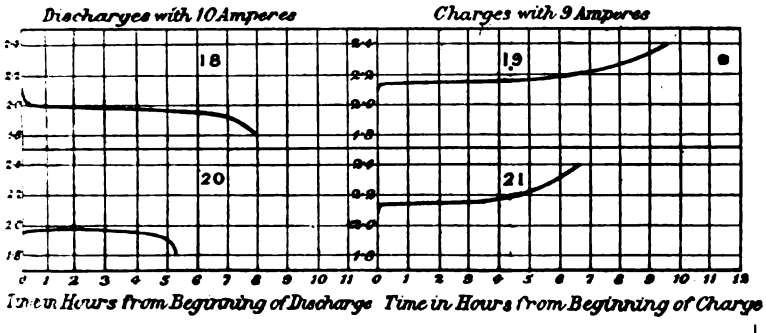

FIG. 6.

In both the instances not only had the potential difference sunk below the normal during repose, but it never quite recovered its normal value, while the fall towards the end of the action took place in about two-thirds of the normal time. On subsequent charging, the process of decomposing the $PbSO_4$ lasted for only two-thirds of the usual time. All this points to an early clogging of the pores, and a consequent diminution of the total chemical action.

In this way we explain what the discoverers of the effect regard as a difficulty. The real problem that had to be solved was not, why did the potential difference go up during discharge? but, why had it gone down during the many days' repose?

(To be continued.)

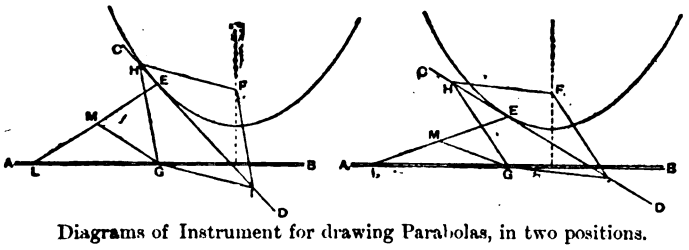
PHYSICAL SOCIETY.

At the ordinary meeting of this Society on the 13th inst., Dr. E. Atkinson, Treasurer, in the chair,

Mr. R. INWARDS read a Paper on

"An Instrument for Drawing Parabolas."

It was designed for drawing curves of short focus such as are required for reflectors and for diagrams of the paths of projectiles, &c. Its construction is based on the fundamental property that every point on the curve is equidistant from the focus and directrix. In the diagram below, A B is a slot representing the directrix, and



Diagrams of Instrument for drawing Parabolas, in two positions.

F G H I a rhombus jointed at the corners and pivoted at F, whilst C D represents a bar capable of sliding through guides at H and I. A rod L E is coupled to G by a bar G M, such that the lengths L M, M E, and M G are equal. As L and G slide along A B the point E describes a parabola whose latus rectum depends on the distance of F from A B. In the instrument, F is carried by a slotted arm, so that its position is adjustable. G E is always perpendicular to A B and equal to E F.

* There may also be a slow formation of lead sulphate on either plate, due to the local action described further on.

Prof. BOYS inquired whether the instrument could be modified to draw any conic section by arranging that the ratio of E F to E G, instead of being unity, might be greater or less than unity.

Prof. PERRY said an instrument for drawing curves represented by the equation $y = x^n$ was greatly needed for engineering work.

Mr. F. H. NALDER exhibited and described

"Some Electrical Instruments."

The first shown was a ballistic galvanometer with one pair of coils, the distinguishing features of which were accessibility, small damping, great sensitiveness, and the arrangement of the control. The control is effected by a "tail magnet," carried on a horizontal tube supported by a pillar outside the case, as suggested by Prof. R. M. Walmsley. A small magnet on the cover serves for zero adjustment. The suspended system consists of four bell magnets, two being in the middle of the coil and one at top and bottom respectively arranged so as to be astatic. The sensitiveness of the instrument shown was such that $\frac{1}{4}$ of a microcoulomb gave 300 divisions (fortieths of an inch) when the periodic time was 10 seconds and scale distance about 3ft. Resistance of galvanometer about 10,000 ohms. To bring the needle to rest quickly, a damping coil mounted on an adjustable stand and a special reversing key with resistances in its base, are provided. The key has successive contacts arranged so that when pressed lightly only a weak current passes round the damping coil, whilst when pressed further a much stronger current passes. The strong currents are used to check the large elongations, and the weak ones for finally bringing to zero. A lamp-stand, with semi-transparent scale arranged for use with a glow-lamp, was next shown. Instead of reading by the image of the filament, as is ordinarily done, the lantern is arranged to give a bright disc of light with a black line across the middle.

Mr. BLAKESLEY asked if the galvanometer was astatic. For damping non-astatic ones he had found it useful to wind several turns of wire round the bobbin, and put them in series with a few thermo-electric junctions warmed by the hand and a key.

In reply, Mr. NALDER said the galvanometer was astatic, but the damping coil could be placed so as to act on one pair of magnets more than on the other.

A Paper on

"A Portable Instrument for Measuring Magnetic Fields, with some Observations on the Strength of the Stray Fields of Dynamos,"

by Mr. E. EDGAR and Mr. H. STANSFIELD, was then read. The instrument was described as an inversion of a d'Arsonval galvanometer, for the torque necessary to maintain a suspended coil conveying a constant current parallel to the field gives a measure of the strength of the field. The constant current is furnished by a Hellensen's dry cell, which the authors found remarkably constant. The instrument consists of a coil of about 50 ohms wound on mica and suspended by two German silver strips within a tube. A pointer is fixed to the mica, and a divided head, to which the outer end of one strip is attached, serves to measure the torsion. Within the head chamber is a commutator, which automatically reverses the current in the coil when the head is turned in opposite directions from zero. Two readings may thus be taken to eliminate gravity errors due to want of perfect balance in the coil. Means are provided for adjusting and measuring the tension of the suspensions.

The authors have tested the fields of dynamos at the Crystal Palace Exhibition and elsewhere, and the results obtained are given in the Paper. It is noted that the stray fields of multipolar machines fall off much more rapidly than those of two-pole dynamos as the distances are increased, and that near edges and corners of the magnets the fields are much stronger than near flat surfaces. The disturbing effect of armature reactions on the strength of the stray fields were measured, and shapes of the fields observed in some cases. Experiments on magnetised watches are described in the Paper.

Mr. WHIPPLE said the Kew Committee were to some extent responsible for the experiments described, for it was on their account that the investigations were commenced. In connection with the rating of so-called non-magnetic watches, it was necessary to know what strength of fields they were likely to be subjected to. The instrument devised for making the tests was a very interesting one, and the results obtained by it of great value.

Mr. A. P. TROTTER hoped the authors would supplement their work by tracing out the directions of the stray fields of dynamos, and he described a simple method of doing this by a test needle used as an india-rubber stamp. Even non-magnetic watches were stopped by being placed in strong fields, owing to Foucault currents generated in the moving parts.

Mr. BLAKESLEY inquired whether the instrument could be used in any position. He thought three observations would be necessary to completely determine any field.

Mr. STANSFIELD, in reply, said they used a pilot needle for showing the direction of the fields, and then placed the coil accordingly. The instrument could be used in any position, for the weight of the coil was only about 2 grammes, and did not greatly alter the tension of the suspension, which was usually about 300 grammes. A watch with a brass balance was uninfluenced by a field of 10 C.-G. S. lines, but seriously affected by one of 40.

THE ELECTRIC RAILWAY SCHEMES IN PARLIAMENT.

JOINT COMMITTEE OF LORDS AND COMMONS.

The Joint Committee of Lords and Commons appointed to consider and report generally upon the Electric and Cable Railway Bills presented during the present Session, met for the second time on Thursday, the 12th. Mr. Stansfeild.

General HUTCHINSON, R.E., of the Board of Trade, said, in answer to Mr. Whitmore, that he had examined the various schemes referred to the Committee. They appeared to follow convenient routes. As to the motive power proposed to be used he had no doubt it would be sufficient for the traffic it was intended to deal with. He formed that judgment principally upon observation of the working of the City and South London Electric Railway. The present schemes were all of them better than the City and South London in regard to the size of tunnels or tubes, gradients and curves. The only suggestion that it had occurred to him to make was that where the tunnels passed under the bed of the river they should have double tubes or skins, an inner and an outer, as an additional precaution against the percolation of water in cases of accident. It would be an advantage if the tunnels were made large enough to admit the ordinary rolling stock of the country, instead of, as proposed, only 11ft. 6in. wide, but it would be a great additional expense. In regard to motive power he might mention that he had had occasion recently to inspect a tramway where the gradient was more than 1 in 14, and he found that the electric power was quite sufficient to take the car at that gradient.

Mr. STORY-MASKELYNE: If the heavy trains that now run on the Great Northern were passed on to these underground lines, have you considered whether electricity would be sufficient to move them unless you had very much larger power than is proposed to be used in these tunnels? It is a very important matter if you cannot work these heavy trains through the tunnels except at an enormous expense beyond what is contemplated.

WITNESS: The only knowledge I have on the subject is that some years ago there was a proposition to use a large engine with electric storage in it for working the trains on the Metropolitan Railway. I understand that in working out the details of that engine it was found to arrive at such an enormous weight that it became impracticable. The idea was therefore shelved.

Mr. J. H. GREATHEAD, engineer to the promotors, recalled, said, in answer to Mr. Gathorne-Hardy, that if the tunnels were made large enough to take ordinary rolling stock it would involve an additional expenditure of £100,000 per mile for construction alone, apart from other matters.

By Mr. STORY-MASKELYNE: Supposing the tunnels were large enough to admit the ordinary rolling stock it would make little difference in cost, whether steam or electricity was used as the motive power.

Mr. CRIPPS, Parliamentary agent for the London County Council, gave evidence to the effect that the Council had no objection to the schemes in the abstract, but wished to make certain recommendations in regard to them. One was that the tunnels should, instead of following closely under the course of the public thoroughfares, be made in straight lines from point to point or station to station. Another was that the tunnels should be made large enough—say 16ft. diameter instead of 11ft. 6in.—to admit ordinary rolling stock and through traffic to the main lines above ground in the event of junctions being hereafter effected. He did not suppose the Council would insist on these conditions if the enforcement of them would make the schemes, from financial or other reasons, impracticable. Another question which the Council had had under consideration was that of ultimate purchase. They considered that clauses should be inserted empowering the Council, as was already done in the case of the tramways, to acquire the lines by purchase after the lapse of a certain period—say, in this case, 60 years.

Mr. A. H. BINNIE, engineer to the County Council, was also examined, and he stated, *inter alia*, that, whatever the size of the tunnels, electric or cable power must be used. The use of steam locomotives would be out of the question.

By Lord THRING: No doubt if conditions are imposed which increase very much the cost of these lines, we may defeat the object we ourselves have in view in promoting cheap communication.

Mr. STORY-MASKELYNE: As to the practical working of these lines by electricity, could you work the heavy traffic—the large carriages that now run on our ordinary railways—with the same sort of installation that would be sufficient for carrying the light trains proposed by the promoters of these Bills?

WITNESS: What the difference in expense would be I cannot say, but the thing could be done.

Lord THRING: Have the County Council considered whether any protection is required in respect to the noise and nuisance that would be created by the electric installation at the terminal stations?

WITNESS: We are asking, should these Bills get to the Committee stage, that clauses shall be introduced bringing the railways under the ordinary Building Acts of the metropolis, which would be some protection to the public.

Lord THRING: I think that protection would only apply to the proper construction of the buildings. Would not the generating station create noise and rumbling which would be an annoyance to the inhabitants of the neighbourhood?

WITNESS: There would be a certain amount of noise and rumbling, but with modern machinery it is very slight. If it should be otherwise, the Companies, like other people, would be liable to actions for damage, and must pay for it.

Lord THRING: But if the Committee authorise the making of a particular generating station it is said there will be no legal remedy for any injury caused by the vibration and noise. Do you think it would be just, in a Bill authorising the construction of these railways, that compensation should be made payable to persons who prove that the noise or other effects of the construction injure their property?

WITNESS: No doubt everyone's property ought to be protected against injury in such a case, although personally I don't anticipate any injurious vibration in regard to these railways. There is very little vibration on the South London Railway: except at the stations where there is a little noise coming up the lifts, you neither feel nor hear it.

Mr. STORY-MASKELYNE: Are not the telephone wires affected?

WITNESS: I believe not in any way.

Mr. CHARLES HARRISON, Chairman of the Parliamentary Committee of the County Council, explained that the suggestions they had put forward were based upon consideration of the probable expansion of traffic and the development of electric science in the next quarter of a century. They were only in the infancy of these things now, and must look forward to the requirements of the future.

The Committee adjourned until Monday.

MONDAY, MAY 16TH.

On re-assembling on Monday Mr. W. H. PREECE, F.R.S., said: I am anxious to bring before the Committee the enormous growth of the electric railway system in the United States. Here in England the first electric railway was constructed in Blackpool in 1885. In the United States in 1884 there was only one road, but they have gone on increasing from year to year until now, when there are 436 roads equipped with 5,851 motor cars. An interesting fact connected with the working of railways in the United States is that there has been no death caused by any of these electric railways, whilst on the steam roads in New England alone there were 5,241 deaths, one half the victims being passengers, and the other half railway servants. I should point out that the great advance in electric railways in the United States has been due to the greater necessity in that country for such locomotion; especially in regard to what we would call suburban tramways. There are no municipal restrictions in that country, and their engineers are eminently practical. When a thing of this kind shows that it is paying they utterly disregard all æsthetical considerations. In fact, in the United States overhead wires are regarded as a mark of progress and civilisation. They do not care much about wires underground. The great reason why railways in the States have made such rapid progress is the fact that they have been a financial success. There is an excellent specimen of an American road at Leeds. I will hand in a complete list of all the electric railways and tramways in the United Kingdom. A great many experiments have been made both here and in America, in trying to work tramcars with batteries instead of horses. This has been done notably on the Barking-road of the North London Tramways and in the central district of Birmingham. The experiment is still in progress. In New York it has been a failure, and the overhead trolley wire has beaten battery traction out of the field. Underground systems of conduit and conductors, such as is in use at Blackpool, have also failed in the States. It was costly to instal and difficult to work, owing to water, snow, mud, and slush. A system—the Lineff—where the conductor is not exposed at all, is about to be tried on the Hammersmith and Kew Road. I have inspected electric railways in Rome, Paris, Florence, Antwerp, Vienna Brussels, Frankfort and Murren. This is all the evidence I propose to give as to the history and growth of the system.

By Viscount BARRINGTON: On all the railways I have been referring to the cars are of the same pattern as the tramcars to be seen in the London streets. None of the railways on the list I have handed in is a tube railway, except the City and South London.

Mr. STORY-MASKELYNE: Are there any in America?

WITNESS: Not one. In America the electrically-worked railways have proved so successful and have had such increased traffic that they have the term universally applied to them—"The factor of public satisfaction." The first reason for working railways by electricity in preference to steam is economy. I shall be able to show that there is no doubt about the economy. The weight carried, for instance, is reduced to a minimum. Inertia is small. Starting and stopping is easy. The power generated is centralised in one spot, and it is applied exactly where it is wanted. The most economical forms of boiler and of engine are available. The mode of working is safe to person and to car. There is no fear of explosion. The electric car is more controllable than a locomotive. It can be backed and sent ahead to make up for lost time, which is not the case with horses or cables, although it is with locomotives. With horses and cables you cannot back easily, and with cables you cannot go ahead. The electric system is flexible and elastic. The air in tunnels is not vitiated by unburnt gases or by the refuse of combustion of coal and coke. There is no smell nor smoke. The conditions in a tunnel are the most favourable to maintain electrical connections. There is no rain nor snow. It is an ideal place. I have no new authentic information as to the cost of the working expenses of these railways, but we may say roughly in regard to all of them that the cost per car mile comes out on the average at sixpence—that is, for a car which, when full, would weigh about ten tons and carry forty passengers. Failures, of course, there have been, and failures are inseparable from pioneer systems, especially when electrical. I have absolute faith in the future of electric railways.

By Mr. WHITMORE: The railways are to be worked on the block system. As a rule the trains have two motors, and any failure is generally due to one of the motors, in which case the other has to do the work alone, and does it, of course, more slowly.

By Lord KELVIN: I understand that for many months past there has been no failure on the City and South London line. Previously trains have been delayed for half an hour or so through the failure of one of the

Digitized by Google

motors, but there are two locomotives that are working now with great satisfaction. Of course the weight of the locomotive must be strictly in accordance with the work it has to do. When I referred to lightness I was referring to the lightness of the cars, and, of course, there would be no tender necessary for coke or water.

By LORD KELVIN: The gradients we meet with in England are nothing compared with those to be dealt with in the United States. There is one place in Alabama, at a place called Nuttion Bridge, where the railway ascends something like 500ft. in one long gradient of 7½ per cent., which is 1 in 13¼. That is far beyond anything we have attempted in this country. It would require about 80 H.P. to ascend that gradient.

By Mr. STORY-MASKELYNE: The difficulty in working an electric railway is the enormous power required at starting.—There is room for improvement.

I suppose they might start the train mechanically without depending on their motor?—Yes.

Lord KELVIN: Does the electric railway cause any disturbance of the telegraph or telephone wires?

WITNESS: We have not experienced, up to the present moment, any interfering disturbance from the existence of the South London Railway; but there is an electrical disturbance that affects the whole of the electrical conditions of London, and it is noticed even at Greenwich Observatory. The records of the Observatory are affected by the working of the railway, and we also, in the Post Office, have been able to observe the alteration in the electric condition of the earth about London upon our service; but it does not interfere with our working, and therefore we attach no importance to it.

Does it upset your signals at all, or ring electric bells?—No, it is never strong enough for that.

Does it affect the telephones?—I have made many experiments to see if there was any disturbance of the telephones, and I can trace none.

Mr. STORY-MASKELYNE: Do you know if any considerable part of the energy of the rails is lost in the circuit?—I am afraid the loss is considerable. At the beginning the points of the tubes were metallically connected, but I think they are not now. It would certainly be difficult to work these railways with a complete metallic current; but if that could be done there would never be the slightest chance of any disturbance. The practical difficulty, however, of completing the metallic circuit on a railway is, as I have said, very great.

Would it not be possible to lay a thin copper sheet under the rail, and carry that through the insulation?—That is done at Leeds. I am not sure whether it is done on the South London.

Lord KELVIN: I understand the occupants of a house next the engine-room of the South London Railway complain of the house being made uninhabitable by the disturbance.

WITNESS: I can speak from some considerable experience on that question. The General Post Office our new building, where all our permanent officials have their quarters, has now in the centre of it four large engines that are used for working the pneumatic tube service of London. The engines are of 600 H.P. They are at work continuously day and night, and yet I am quite sure if you were to ask any official in the Post Office where the engines were he would tell you he did not know of their existence. Again, in the large building at St. Martin's-le-Grand, where all the letters are sorted, there is 1,000 H.P. used in producing electricity for the lighting of the place (we supply 10,000 lamps), and that causes no noise. This Committee might at the present moment be sitting over that engine-room with all the machinery going and not experience any disturbance at all. There are eight high-speed engines, and frequently five or six of them are going at once; in fact, it is just such a central station as would be required for working the proposed Waterloo and City Railway.

And the vibration proceeding from those engines is not inconvenient?—It is not perceptible.

How far from the engine-room is it not perceptible?—It is scarcely perceptible outside the engine-room. We have another central station at our Savings Bank Office in Queen Victoria-street. Close by our office there is the office of a firm of solicitors who complained of disturbance, alleged to be due to the vibration of our engines. We had a good deal of trouble over the matter, and ultimately found that the disturbance was not due to our engines at all. It was traced to the Metropolitan Railway, which runs under Queen Victoria street some 250 yards from the solicitor's office, whereas our engine-room is only 20 or 25 yards. In our investigations into that matter I found the most convenient instrument for testing the vibration of a building was a simple glow lamp. We have complaints as to smoke, and the British public have not yet learnt to distinguish between the vapour of steam and the black smoke of coal. We are now putting in a contrivance to enable us to burn anthracite, which does not give smoke. I think if we do not send up smoke the complaints as to mere steam vapour will not be so serious. The South London Railway is free from smoke, and I have not heard of there being any complaints as to steam vapour.

Would the electrical advantages on these new railways be affected by the question whether the tubes were the same size as those of the South London or much larger?—It seems to me that the tubes of the projected Waterloo and City Railway, 12ft. in diameter, are ample for such purposes as these railways are promoted to serve.

Do you think it would be a great advantage that the tubes should be made very much larger, so as to allow ordinary railway trains to pass through?—I think it would be a distinct disadvantage. These railways, it appears to me, are to be put down solely for the benefit of urban passengers—not for through passengers or goods—and the size of the tunnels on the proposed railways would be large enough. If the tubes were larger, the stations and the whole of the plant would have to be larger in proportion, and so the cost would be greatly increased.

Viscount BARRINGTON: Would there be any advantage in having the tubes of all the railways of an uniform size?

WITNESS: I do not see that it is necessary, as it is not proposed to connect the different lines.

By the Earl of LAUDERDALE: The average speed of working on the South London is about 15 miles an hour; on the City and Waterloo it will be about 20. It is proposed on these new railways to work on the block system, and to have intermediate blocking stations between the ordinary passenger stations.

By Mr. STORY-MASKELYNE: As it is impossible to tell what developments may come about in the future, it might be desirable to construct these lines on the same bases as to size of tubes, &c., although there appears no immediate necessity for doing so.

By Lord KELVIN: As the up and down lines are in separate tunnels, the danger of trains fouling the lines does not exist. The block system is easily worked on electric railways, and could be made automatic.

By Mr. STORY-MASKELYNE: I see no reason why the tubes, where they pass under the bed of the river, should have double casings.

Mr. ALEXANDER SIEMENS was called to speak specially as to the Great Northern and City Electric Railway, which was designed to carry through the Great Northern traffic to the City in Great Northern rolling stock. Whilst a South London train weighed about 70 tons, a Great Northern would weigh 180 tons. As Mr. Preece had already pointed out, a locomotive must have a certain weight—about 45 tons in this case—to acquire the necessary power to make such heavy trains go. His firm had gone carefully into that question. They could build electric locomotives of the necessary weight and power to start such trains of 180 tons, and run them over the line where the steepest gradient was 1 in 66. The dynamo electric machines had the good quality that they could exert very great power at starting. The fact that the trains weighed 180 tons constituted no difficulty in the way of working with electrical locomotives, because it depended simply on the motor having sufficient power to move the train, and there was no difficulty in getting 600 H.P. He had gone into the question of cost. Assuming that the journey from Finsbury Park to the City whould have to be done in 10 minutes, he found the cost of the motive power would be between 10d. and 1s. per train mile for 180 tons. That was a very ample allowance.

The CHAIRMAN: That is nearly double the train mileage on the South London?

WITNESS: Yes. That has come out at nearly 7d., but the charges there are still somewhat high. We think we could work the 180-ton trains at 10d.

The Earl of LAUDERDALE: At what rate of speed?

WITNESS: An average of about 18 miles an hour. In 1889, at the request of Sir John Fowler, I went into the question of working the Inner Circle trains by electric motors, and within the last few days I have gone into the matter again in the light of the experience we have gained on the South London. I found there would be an outlay necessary of about £150,000 to supply 20 electrical locomotives, conductors, generating stations, and everything complete to take the 14 trains that are running on the Inner Circle Railway at the speed they are now going; and then the cost per train mile would come out at about 8d.

The CHAIRMAN: How does that compare with the cost of the present system?

WITNESS: About the same. Perhaps the present cost is a little more.

Mr. GATHORNE-HARDY: Then there would be no great advantage?

WITNESS: No.

The CHAIRMAN: Do I understand that electricity is as applicable as steam power to heavy trains?

WITNESS: Yes, certainly; but the outlay for generating plant, conductors, &c, is very heavy—so heavy that it would not pay to run heavy trains by electricity unless they were very frequent; and of course that could only be done if there were sufficient passengers.

The Earl of LAUDERDALE: Ordinary locomotives could run at short intervals the same as the electric?

WITNESS: Yes; I don't see any difference.

Then if there was an increased number of passengers in the one case and it paid, the same thing would happen in the other case?—Yes; but when you have sufficient traffic to justify frequent trains, the electric power comes cheaper than steam power. It would not pay, for instance, to run heavy trains to Liverpool or Manchester by electricity with the present limited traffic, although, leaving the question of profit out of sight, it would be quite feasible to do so.

By the CHAIRMAN: The electrical trains would be easier to control than the steam. The motive power of electricity is better adapted than steam to the running of very light trains. As to the size of the tubes I think that for simple passenger traffic they ought to be made as small as can conveniently be done. I think the City and South London tubes are rather too small in diameter, and that 11ft. 6in. would be an improvement. I think the tunnels should be as small as they can conveniently be made, because of the important question of cost.

By Mr. STORY-MASKELYNE: As to the question of uniformity of diameter my private opinion is that it would be best to have the tubes all alike. At present there is no idea of connecting them, but it would be better not to exclude the possibility of its being desired in the future.

There would be no inseparable difficulty about securing such uniformity?—No.

If they were to be all of the same width, what would you say that that width ought to be?—I should say a little wider than the South London—say about 12ft.

It would not occur to you to suggest that they should all be 16ft. wide?—No, I think not. There are special reasons for it in the case of the Great Northern and City Railway, but I think in regard to the other lines it would make them unnecessarily expensive.

Lord KELVIN: What electric pressure would be used on these lines?

WITNESS: I believe that for the present the same pressure is contemplated as is used on the South London, viz., 500 volts; but in view of

Digitized by Google

the greater length of the lines, I should say it would be better to employ 1,000 volts.

In that case would it not be better to have the currents overhead? Otherwise, in case of accident, would it not be dangerous if passengers were walking about in a tunnel when there was a current of 1,000 volts in the middle rail?—In case of accident the current would be cut off.

You are decidedly of opinion, all things considered, that 1,000 volts would be preferable to 500?—Yes. I am looking at it entirely from the standpoint of cost.

Would it not be as easy to have the conductor overhead as underneath the train?—Yes, and that was our original proposal on the South London line.

If 1,000 volts were used there would be some danger?—Yes; it is bad enough with 500.

That is, you might not be hurt by a current of 500, but with a current of 1,000 you would be seriously hurt?—That somewhat depends upon the individual. It would be safer, if circumstances would permit, to have the conductor at the top of the tunnel. The difficulty on the South London would be in regard to insulation, owing to want of space. The putting of the conductor in between the rails was more convenient in that instance.

Supposing a railway porter or signalman was to trip accidentally whilst in the tunnel, and fall across the rails, with the current of 1,000 volts passing through, what would happen?—It might depend on the state of his clothing.

Suppose it was very wet?—I think it would make him jump up.

You think he would jump up? Suppose his head struck the conductor?—As I have already said, a great deal depends upon the individual. Some can stand a great number of volts.

You think some would jump up; but would not a large proportion be killed?—Some might be killed. I should expect them to be burned.

Suppose it was to be ruled that where the conductor was on the ground the voltage should be limited to 500, and that where the voltage was more it should be compulsory to have the conductor overhead?—I think that would be a very good way of giving an alternative.

Mr. STORY-MASKELYNE: Does the Board of Trade require any particular voltage on lines in the streets?

WITNESS: I think they allow 300, but if you want more you can make special representations. I believe they will sanction 500.

If we insisted on a lower voltage, would that mean an increase in the number of stations?—It would be a question of money—whether it would pay better to put more generating stations, or to have larger conductors. It would mean great cost, anyhow.

But the difference of cost would not be prohibitive?—Oh, yes, it might be.

Do you know the amount of the difference it would make in the cost?—I could not say offhand.

Mr. GREATHEAD: In the case of the City and South London, the Board of Trade inspectors went thoroughly into the question of where the conductors were to be, the voltage, &c., and they inspected the line before it was opened to the public. They allowed us 500 volts, and we work with 500.

Mr: GATHORNE-HARDY: Would there be any difficulty in putting your conductors at the top of the tunnel?

Mr. GREATHEAD: Only that it takes away so much of the headway from the carriage.

Mr. CHARLES H. SCOTTER, general manager of the London and South-Western Railway, gave evidence as to the necessity of improved facilities for passenger communication between Waterloo and other parts of London. He believed the proposed electric railways to the City and Baker-street would go a long way towards solving the difficulty; and the schemes, on account of their comparatively small cost, would, he believed, be quite practicable.

Mr. W. N. COLAM gave evidence in support of the Hamptead and Charing Cross Cable Railway.

The CHAIRMAN intimated that the Committee would require no further evidence as to the desirableness of the routes of the proposed lines; and

The Committee adjourned until Wednesday.

WEDNESDAY, MAY 18TH.

On Wednesday, Mr. J. WOLFE BARRY, Engineer to the Corporation of London, was the first witness. He stated that, in conjunction with Col. Heywood, he had been requested by the Corporation to report upon the railways from a strictly public point of view. The first part of their report being descriptive, he would not touch upon it, as that side of the question had already been dealt with. The first question submitted to them was that of the depth at which these iron tubes ought to be placed; and their recommendation in that matter was that no portion of the railway tunnels should be less than 10ft. below the undisturbed surface of the London clay. In his judgment it was very essential that a clause to that effect should be inserted in the Bill, because the safety of the adjoining buildings depended altogether upon these tunnels being kept well down into the London clay. He thought the promoters of these schemes recognised that to a certain extent, and he believed the intention was to keep below that level. The reason why they should keep the tunnel below the London clay was that it was a stratum which was practically impervious to water; and, except for accidental depressions and cracks, which were very rare, and would not extend more than 10ft. below the surface, very little difficulty in tunnelling was experienced. Whereas, if they attempted to drive these tunnels in water-bearing strata, the whole problem was entirely different, and involved much more serious risks to property; and it was obvious that if a tunnel was not laid at a great depth below the road level, the houses adjoining and streets, 40, 50, or 60ft. wide, would be affected. The next point which the Committee asked their opinion upon was the diameter of the tubes, which was a most important question. There were two questions, the uniformity of gauge and the absolute size of the tunnels. Legislation with regard to this, up to the present time, had been somewhat haphazard. In the case of the City and South London Railway, the tubes, he thought, were intended originally to have a diameter of 10ft.; their Bill was introduced into Parliament as a cable tramway rather than a railway, and it was subsequently worked by electric motors. In the Act for the extension to Clapham, passed in 1890, this 10ft. diameter was secured. Last year a Bill was deposited by the same Company which proposed a diameter of 11ft.; that was not passed, but the Central London Railway Bill was passed with a diameter of 11ft. 6in. This year they had various Companies, proposing diameters of 11ft. 6in., 12ft., and 16ft. The Baker-street and Waterloo Railway proposed a 12ft. diameter, the City and South London 11ft. 6in., and the Hampstead and Charing Cross line 11ft. 6in.

By Lord KELVIN: He supposed the reason why the engineers recommended the smaller size was that they found the larger ones not suitable to curves and matters of that kind, and having regard to the question of rolling stock. If they had a very small tube, however, it resulted in a very high amount of air resistance. He would insist upon uniformity of tube, and would recommend that they should be made large enough to carry the ordinary rolling stock of the country. The tubes ought to be a little larger where the curves were short.

Continuing: He wanted to establish a minimum size. The third question was the adequacy of the proposed railways for the present and future traffic of London. They agreed that there could be no question that a very large traffic could be carried by these railways. At the same time they did not think that the lines could be expected to carry the traffic as easily and conveniently as ordinary railways. The fourth matter was the question of communication between the several railways proposed and existing railways. At present the proposals before the Committee, except in the case of the Great Northern and City Railway, which not only joined the Great Northern Railway system, but sought for running powers over a portion of their system, there was no connection with railways; they were in juxtaposition to existing lines, but not connected. The Corporation thought this question of junctions was one which merited the most careful consideration of Parliament. Then, as to the desirability of a central station at the Mansion House, their view was entirely endorsed by the Corporation; there was no doubt the Mansion House had many advantages for receiving and distributing the traffic of these railways; but, on the other hand, the site was a greatly congested spot. By the Bills under consideration three railways would have their termini or stations at the Mansion House, and at the busy times of the day each would develop a very large traffic. The traffic would not be spread uniformly over the day, it would be generally concentrated for about two hours in the morning and two hours in the evening; and although these railways would not require much vehicular accommodation, the centralisation of foot traffic might at times be found inconveniently large, when all the stations were working their full power between 9 and 11 o'clock in the morning, and from 5 to 7 in the evening. It was proposed in the Mansion House site that there should be a circular gallery and a booking office underground for passengers and lifts, and the public would also have the right to cross through these galleries to cross the roads. The City viewed that with some considerable alarm as a great concentration of traffic. The station would be constructed, as he apprehended, in the London clay by the use of shafts. But, in addition to that, the whole of the site was intersected by gas and water pipes of a very important character, and it would be necessary to construct a subway about 250 yards in length below the street, and into that subway would have to be laid a complete set of new gas and water mains before any of the old ones were interfered with. He should like to say that if these Bills went forward they ought to be adequate to carry the rolling stock of the country, and he considered that at present a break of continuity was proposed which approximated very nearly to a break of gauge. Looking ahead and at this subject from a broad point of view, these lines might be good lines in themselves if they were made a proper size, and as to the cost, he did not wish to quarrel particularly with the figures which he understood were indicated.

By the CHAIRMAN: The capital of the Waterloo and City line provided for a cost of £258 a yard. He would propose an extra cost. Supposing the extra cost of the tunnels varied as the square of their diameters, he did not endorse the idea that a 16-foot tunnel was required. On this principle the line he had mentioned would cost £314 a yard, or an addition of 22 per cent. on the total capital. The Hampstead and Charing Cross Railway treated in the same way would require an addition of 25 per cent. of the total capital. He thought even if the addition was considerably more it would be money well spent in the interests not only of the public but of the shareholders. A railway which was able to carry all the traffic of the country was, he thought, double the value of one which could only carry strictly urban traffic. Touching on the question of fares he mentioned that at present the urban fares of the Metropolitan District Railway were scarcely remunerative. Since the omnibuses and trams had been competing with them their remuneration had dwindled in a remarkable way, and they relied a great deal on their extension into the country. If electricity was to be the mode of working, it could just as well be applied in a large tunnel as a small tunnel. He did not think they could look forward to an electric railway working more quickly than the Metropolitan Railway, which was about 20 trains an hour, and on boat-race day perhaps they might reach 24 or 26 an hour. The trains of the District Railway frequently carried 400 passengers at certain times of the day, owing to people standing up in the carriages.

By Lord THRING: There was no place in the world where traffic required so much accommodation as London at certain times of the day. He thought if the suggestions he had made were carried out the schemes

Digitized by Google

would be very much more valuable. He did not ask the Committee to throw out the Bills, as he thought it would be a great pity to abandon them; but the connections with existing railways was a most important point, which he thought ought to be provided for if the Bills went forward. He admitted that if carried out they would greatly relieve the congested traffic of the streets.

Sir DOUGLAS FOX, Engineer to the Hampstead and Great Northern and City lines, was the next witness. He drew attention to the fact that the question of the introduction into an important city of a subsidiary system of lines had been very fully considered in New York, resulting in the introduction of an auxiliary system of overhead railways. The principle in the two cases was the same. The overhead lines were not so constructed as to accommodate the rolling stock of the main line, being neither of sufficient strength nor having curves of a requisite radius. These lines carried at the present time about 200 millions of passengers per annum, entirely independent of direct junction with the existing main lines. The question had also been considered in Liverpool, where they had an overhead railway six miles in length, running through Liverpool from end to end; and there this same question cropped up, as to whether it was necessary or desirable to incur the increased cost of making the line suitable for carrying the ordinary rolling stock, and the conclusion had been that it was not desirable. When the Inner Circle scheme first came before Parliament, it was proposed that it should be an inner circle with junctions. The large number of outside trains called into the system introduced irregularities and delays. Whilst they might be profitable to the companies, he did not think they increased the efficiency of the service. It had been said that these trains could not compete with omnibuses, but he ventured to think one reason for that was the bad ventilation. The Great Northern and City Company proposed to make their diameter 11ft. 6in., but with an increased diameter on the curves of 12ft. If the tunnels could be made of sufficient diameter to carry main line stock at the same cost, the question of additional cost would hardly arise. Mr. Barry had said that the cost of the increase was the square of the diameter of the tunnel; but if they worked it out they would find that a 12ft. tunnel worked out to £144 and a 16ft. tunnel to £256, which was very nearly double. The cost of the Inner Circle, taking the whole of it, might be put at not far short of £1,000,000 a mile. The estimated cost of the Great Northern and City Railway, with a 16ft. tunnel, was £650,000 a mile; the estimated cost of the Hampstead line, which had a 11ft. 6in. tunnel, was £370,000 per mile.

The CHAIRMAN: Do all these equally include rolling stock?

The WITNESS: Yes.

Lord THRING: Do you mean these sums would mean putting the railways in actual working order?

The WITNESS: Yes, the total capital expenditure, stations, rolling stock, line, and everything. He was convinced that this difference of cost which Mr. Barry proposed for those lines which were intended as purely passenger lines, would be prohibitive, and it would not be possible to raise the money nor to construct those lines in such a way as to take the main line traffic of the large companies. The one exception was the Great Northern and City scheme. He did not see how it would be at all possible to utilise the Hampstead line, supposing they could make junctions with the four existing lines, connecting at one end with the South-Eastern Railway and at the other end with the London and North-Western, Midland, and Great Northern Companies. For a railway which was specially designed for running three-minute trains for local traffic, it would be to introduce confusion and delay, which would practically destroy the utility of the railway as a railway for local traffic. With reference to the Great Northern and City Railway, it was under the consideration of the Committee because it was proposed to work it by electricity, otherwise it was an ordinary extension of an existing railway system to a railway station in London. It was promoted because the Great Northern Railway district, which was one of the finest suburban districts anywhere near London, had only two accesses to London, one over the Metropolitan Railway through King's Cross, and the other over the North London Railway to Broad-street, and both at this moment were completely congested. The trains running at the busy times of the day carried far more passengers than they ought to carry; and yet there was a constant outcry from all persons interested in these particular suburbs that they were not properly served. This scheme was to enable the Great Northern to project an entirely new system of trains of their own from this district, and new districts which they proposed to open up to this station in Moorgate-street. They had considered very carefully with Sir Henry Oakley the diameter of tunnel. If they had adopted the smaller tunnel, they would have had to go to Finsbury Park in order to make a proper exchange station, which would have involved an additional length of at least one mile of railway tunnel. It would have given them a very expensive underground station at Finsbury Park, instead of an open one at Drayton Park; and they would have had an exchange traffic by hydraulic lifts, instead of as at present by ordinary means. They would have had also to provide electrical plant for an additional mile of railway, quite unnecessarily, as the Great Northern Company were willing to run into Drayton Park, and they strongly objected to duplicating their line between Finsbury Park and Drayton Park. It so happened that the conditions surrounding the proposed station were such that they were able to make a line with a comparatively easy gradient from an ordinary junction of the Great Northern system. Another very important consideration was that the Great Northern were willing to allow their suburban trains to run over their line, and their Company thus would be saved the cost of supplying their own rolling stock. They had found that in this particular instance it would be as cheap to make a line to join the Great Northern with an ordinary junction and a large tunnel as it would have been to make a smaller tunnel with the greater length to the exchange station. The exchange station was generally better than a junction. With regard to easements under property where the property was not affected, they had always been taken to represent a considerable value; therefore, if the railways were carried direct from point to point the compensation, in his opinion, would be very large. He could not understand what had been said about taking the subsoil out of the streets. The public would be very great gainers by the companies taking the subsoil. At present it made no return to the rates, but as soon as these railways were made it would be rated, and the streets would become very valuable property. Neither the omnibuses nor the tramcars paid anything for their rights of running over the surface of the streets; whereas the railways, which did not affect the traffic, were going to pay a very large amount to the rates. It had been proposed by Mr. Barry that the depth of these tunnels should be fixed 10ft. below the undisturbed surface. He thought that, from an engineering point of view, that proposal was unworkable. With certain properties the owners might ask that such a clause might be inserted where the depth of the clay was low.

The CHAIRMAN: Would you propose that there should be no such limitation?

WITNESS: Yes; I do not think it is necessary.

By Lord STRAFFORD: He thought the tunnels would be out of the clay in some places. He did not come there as an electrical expert, but he would like to say that the Liverpool Overhead Railway Company, which had already been referred to, after considering tenders for steam and electricity, decided upon adopting electric traction for their line.

By Lord KELVIN: He personally should prefer electric traction. If the gradients were not too severe electric traction would be more economical than the rope traction, he thought.

Mr. W. R. GALBRAITH, Engineer to the City and Waterloo, and Baker-street lines, was then examined, and said with regard to the advisability of a junction of the Waterloo line with the London and South-Western Railway, that if an underground railway was made between the City and Waterloo, a junction with the London and South-Western Railway at Waterloo was impossible. He did not know where such a junction could be made, and any new line from the London and South-Western Railway to the City which joined Waterloo would be practically useless, because unless a train were split up at some point south of Waterloo, and a portion run into Waterloo and a portion into the City, it would be no use.

By Lord KELVIN: Tubes 12ft. in diameter were quite as good as 11ft. 6in. tubes for passenger purposes. He did not think there was any great merit in making the diameter of the tubes identical.

Mr. F. HUNTLEY was then called as a witness. He considered the proposal that the subsoil should not be allowed to be used without compensation being made a most objectionable one.

The Committee then adjourned.

LEGAL INTELLIGENCE.

Western Counties and South Wales Telephone Company v. Bournemouth and District Electric Supply Company.

In the Chancery Division on Friday last, the case of the Western Counties and South Wales Telephone Company v. Bournemouth and District Electric Supply Company, came before Mr. Justice Chitty, in the form of a motion by the plaintiffs, asking that a writ of sequestration should be issued for an alleged contempt of Court committed by the Bournemouth and District Supply Company, in wilfully disobeying an order of the Court, dated April 8th last, directing that the defendants should be perpetually restrained from working or using their electric lighting system, apparatus, and work, in the town and neighbourhood of Bournemouth, in such a manner as to injure or interfere with the plaintiffs' exchange system, and in particular from causing or permitting injury to the plaintiffs' system either by induction or leakage, or from any other cause connected with the defendants' inductors.

Mr. FARWELL, Q.C., who appeared for the plaintiffs in support of the motion, said this was a most important case for his clients, as they could not work their telephones in a proper manner after the defendants had turned on their electric current.

Mr. BYRNE, Q.C., on behalf of the defendants, applied that the case should stand over for a week. He was not at present in a position to say anything about the matter.

Mr. FARWELL said the telephones were absolutely useless, and, therefore, he asked that the defendants should give an undertaking not to use their electric light until next week.

Mr. BYRNE said when the motion was before the Court on a previous occasion the defendants were directed to put their wires underground, and they had done so.

Mr. FARWELL remarked that this was a case in which one of the companies must suffer the inconvenience of having their system practically stopped. He submitted that the plaintiffs ought not to be asked to stop their works. He wished to point out that the electric light was used for lighting, not the town, but some private buildings. The telephone system was of more importance to the people of Bournemouth than the electric light. If the defendants were not put under an undertaking not to use their electric light for a week, he would ask that they should not start their current until eight o'clock at night; and that an independent gentleman should go down to see what was being done, and file an affidavit to be used next week. He suggested that Major Cardew, of the Board of Trade, should be asked to inspect defendants' system and make a report.

Mr. BYRNE said he could not give any undertaking, as at present he did not know the whole of the facts.

His LORDSHIP said Mr. Farwell had done his best for his clients but he (the learned judge) could not place the defendants under any undertaking. The motion would stand over till this day (Friday).

Love v. St. James and Pall Mall Electric Light Company, Limited.

In the Chancery Division of the High Court on Saturday, before Mr. Justice Stirling, a motion in the action of Love v. St. James and Pall Mal-Electric Light Company, Limited, came on for judgment.

His LORDSHIP said that the motion was one for interim injunction to restrain the Company from building, at their new central station in Carnaby-street, in such a manner as to interfere with the rights of the plaintiff for light and air to premises of which he was the owner. Since the 29th February communications had been passing between the parties, and so early as the 17th March the plaintiff had represented that the elevation of the proposed new front wall would be two feet higher than the height of the old buildings which it would replace, and that this would be a great injury to his property. The architect to the defendants replied that the plaintiff was in error in supposing that the new building would exceed the height of the old, and would cause any substantial deprivation of light. The defendants maintained this position and attitude until the action was brought, and this motion was made. It had since appeared that the plaintiff was right, and that the new building would have been two feet higher than the old, and thereupon the defendants gave an undertaking, and an arrangement was come to by which the action was stopped, and all that had now to be dealt with was the costs. His lordship thought that the result showed that the plaintiff had been justified in bringing his action, and that the action was reasonable. The plaintiff, on April 13th, accepted an undertaking from the defendants that they would not build otherwise than with certain altered plans, which they then exhibited; and thereupon the action came to an end, except upon the question of costs. In these circumstances the question to be decided was whether anything the plaintiff had done was so unreasonable that the Court ought to deprive him of his costs. His lordship thought not. He thought that the plaintiff had reasonable grounds for bringing his action because of the defendants' architect persisting, down to the date of the action, in his erroneous view as to the height of the old buildings. He therefore held that the general costs of the motion should be borne by the defendant Company.

An order was made accordingly.

Electric Arms and Ammunition Syndicate (Limited) v. Pooley

This was an action before Mr. Justice Grantham and a common jury to recover the sum of £83. 0s. 6d., calls on two shares in the above syndicate, which the defendant alleged he was induced to take by statements in the prospectus, and which he pleaded had turned out to be false; and he therefore asked to have his contract rescinded, or in the alternative he claimed damages for misrepresentation.—Mr. Willis, Q.C., was leading counsel for the plaintiff syndicate, and Mr. Jelf, Q.C., for the defendant.—A long legal argument took place on the first day as to whether the defendant had any legal defence, and in the result his lordship decided to hear evidence. Accordingly, on the second day the defendant himself went into the witness box, and, having given his evidence and the question of his legal defence having again come up for discussion between counsel, the jury asked his lordship whether the case could not be stopped, as they had made up their minds that the defendant had acquiesced in all that the syndicate had done, and that, therefore, he could not claim against the syndicate, as he was himself a member of that syndicate, and to that extent jointly responsible for the actions of its members, including the Directors.—His lordship, after consultation with counsel, found for the plaintiff syndicate with costs, and agreed with the jury that there had been no fraud on the part of the Directors, but that the prospectus was issued in good faith, and was thoroughly believed in by them. There was, therefore, no evidence to support the charge of fraud which had been so freely made by the defendant. The main feature of the action was the evidence which went to show that the chief difficulty experienced by the syndicate was the discovery of a battery suitable for firing small arms.

Hopkinson v. The St. James and Pall-mall Electric Supply Company (Limited).

Application was recently made by the plaintiff in this action for answers to a set of fourteen interrogatories by the defendant Company's engineer, and the Chief Clerk decided that the Company could not be required to furnish the answers. The plaintiff on Monday appealed against this decision, which was, however, upheld by Mr. Justice North, excepting as regards the first interrogatory, which required the Company to say whether or not their circuits are arranged in the manner described in the second claiming clause of the plaintiff's specification.

In re the International Cable Company (Limited).

In Chambers on Monday last, the question as to the party liable for the costs incurred in the inquiry as to the amount of fees to be paid to the Directors for services rendered between the date of the presentation of the petition for winding-up and the date of the winding-up order (a period of about six months), came before Mr. Justice Stirling; and in the result his lordship ordered that the Directors were simply to be paid with the other creditors of the Company, and he also directed that Sir Alexander Armstrong's costs of this application be added to his claim.

On Wednesday, in the Court of Appeal, the decision of Mr. Justice Stirling in the action of the International Cable Company (Limited) v. Suren and others was mentioned; and his lordship's judgment being considered by the appeal judges to be irregular in its language, as it left some doubt as to the disposition of a sum of £250, it was referred back to his lordship for amendment.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May 7*, 1892.

Rumoured Electrical Manufacturing Consolidations.—During the past week rumours have again been afloat of the coming combination of the Westinghouse Electric and Manufacturing Company and the Siemens and Halske Electric Company of America. It has been emphatically asserted on good authority that such a combination was about to be made, but New York parties connected with both of these companies have denied the report as utterly false.

The Western Union Company and the Telephones.—The annual meeting of the stockholders of the Metropolitan Telephone and Telegraph Company, the organisation which operates the telephone system of New York City, was held this week. Among the Directors elected were Thos. T. Eckert, Geo. J. Gould and Norvin Green. This merely serves to show what an intimate business connection there is between the telephone business of this country and the business of the Western Union Telegraph Company.

The General Electric Company.—The General Electric Company, the result of the Thomson-Houston and Edison combination, has been formally organised. The election of the new officers took place in Boston on Tuesday of this week, and resulted in Mr. C. A. Coffin being elected president, and Mr. Eugene Griffin vice-president and general manager, with Mr. Samuel Insull as second vice-president.

The New Edison Telephone Patent.—The telephone patents, about which rumours have been in circulation for three weeks, were issued on May 3rd. These are three patents applied for by Mr. T. A. Edison on July 20th and April 20, 1877, and were assigned by him to the Western Union Telegraph Company; that Company in turn disposed of them to the American Bell Telephone Company. It turns out that the patents are the same as those which were granted to Mr. Edison in nearly all European countries in 1877. It is generally admitted by American authorities that the claims of the patents, or a part of them, are very broad, and that if they can be sustained they will give the Bell Telephone Company an extension of its present monopoly. The question arises, however, as to the validity of the patents, since the foreign patents for the same invention had already expired when these patents were granted. How the matter is viewed on this side of the water may, perhaps, be best gathered from the following extracts taken from an article in the *Electrical World*:—"The case may then be summed up as follows:—According to our laws a United States patent expires with the date of expiration of the shortest termed foreign patent: everybody knows this law when they make application. Edison has, according to the requirements of the office, stated under oath that this invention was the same as that patented by him abroad; there can therefore be no question raised about its being a different patent; that 'trick of the trade' which is sometimes made use of to evade this law cannot therefore be made use of in this case. . . . But the question arises how the 'letter of the law' can be applied in case the United States patent is not issued until after this term has expired. This appears to be the first case of the kind on record. . . . The Bell Company may put in the plea that they have, through no fault of their own, been deprived of the patent protection for this patent for 15 years, and that they ought, therefore, to be allowed protection for 17 years from date. . . . But even admitting that the law could be twisted so as not to make the patents invalid, there still remain other unexpired foreign patents for this which will expire shortly, and which, according to the law, will make the United States patents expire very soon. No amount of argument can change this, unless the law be changed completely. The latter is a possibility. Edison has already expressed himself as dissatisfied with this law, which has affected him unfavourably before, and he wishes to have it changed. This attempt has been made before, but the Supreme Court has decided in favour of the law in all the cases. There is no telling, however, whether this wealthy and powerful Company, who have accomplished so

Digitized by Google

much in the Courts already, might not prove to be more powerful than the Courts or Congress, and gain their point by some means. Congress may be appealed to, and if it wishes it can do what it pleases, or whatple ases the Company, but it is very questionable whether the Company would succeed in this way; it would be an expensive proceeding. But they have been so successful in the Courts that they may feel encouraged to try anything, without regard to principles, law, or equity. We have been suffering for years with a very unsatisfactory telephone system, operated purely for money, without any regard for the kind of service. In other civilised countries the Government has stepped in, here it has not; and it is a question now what the Government will do when it gets a chance to relieve the public of a most objectionable monopoly."

CORRESPONDENCE.

AN ELECTROLYTIC EXPERIMENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On page 28 you extract from *La Lumière Electrique* an account of an experiment "due to Herr Arons, and shown by him to the Berlin Physical Society." It is the rotation of a copper cylinder, under the influence of electrolysis, dissolving one side and depositing on the other. Now, doubtless, Herr Arons discovered this for himself, but, none the less, the discovery is not "due" to him. It was discovered by myself, and included in a patent of mine, No. 4,454 of 1881, where I described a meter working on that principle: "I construct an electrolytic cell with a pair of electrodes, and mount between them upon suitable bearings an 'induced electrode' in the form of a cylinder, so that it can rotate freely when the deposit on one side and solution on the other alters its centre of gravity." I gave a drawing of the apparatus, with contrivances for directing the action upon the most effective parts of the surface of the floating cylinder, *i.e.*, the ends of the horizontal diameter.

I had discovered the fact and used it experimentally many years earlier in the form of a disc rotating in this manner between two electrodes.—Yours, &c., JOHN T. SPRAGUE.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—Our advertisement columns contain an announcement that the Dundee Gas Commissioners are prepared to receive tenders for the execution of the following six contracts in connection with the proposed supply of electric light to Dundee under Provisional Order:—1, boilers; 2, steam piping, &c.; 3, steam engines; 4, dynamo machines; 5, accumulator batteries; 6, street mains. Tenders are to be delivered to Mr. T. Thornton, clerk of the Commissioners, by the 31st inst.

——— Tenders are invited by an announcement in our advertisement columns for complete machinery for 100 incandescent lamps for the existing power, packed and put f.o.b Birkenhead or London. Tenders are to be sent to the Indentors Union (Limited), 4, Bury-court, St. Mary Axe, E.C.

——— Tuesday next, the 24th inst., is the day fixed for sending in tenders for the Glasgow contract. (See advertisement on page xix.)

TENDERS ACCEPTED.—The following tenders were received for the Bristol work (see *The Electrician*, May 6, p. 4). (1) Supply, delivery, and erection of steam alternators and steam dynamos:—

India Rubber, &c., Co. (Ltd.) (continuous only)	£21,090	0	0
W. T. Goolden and Co.	20,087	0	0
Brush Electrical Engineering Company (Limited)	19,495	0	0
Electric Construction Corporation (Limited)	16,175	0	0
Blakey, Emmott and Co.	15,954	0	0
Paterson and Cooper	15,826	0	0
Mather and Platt (Limited)	15,434	0	0
Crompton and Co. (Limited)	15,141	0	0
Johnson and Phillips	14,357	0	0
Woodhouse and Rawson United (Limited)	14,327	0	0
Latimer Clark, Muirhead and Co.	14,053	0	0
Siemens Bros. and Co. (Limited) (accepted)	14,011	0	0
S. Z. de Ferranti (Limited) (alternators only)	12,687	0	0

(2) Supply, delivery, and erection of boilers and accessories:—

E. Finch and Co.	£10,500	0	0
Hawksley, Wild and Co.	9,723	0	0
J. Thompson	9,500	0	0
Newall and Co.	8,999	9	6
Fraser and Fraser	8,614	0	0
Woodhouse and Rawson United (Limited)	8,063	10	0
Oldham Boiler Works	8,060	0	0
Yates and Thom	7,665	0	0
R. Taylor and Sons	7,504	0	0
Tucker Bros. (accepted)	7,300	0	0

——— Messrs. Crompton and Co. (Limited) have secured the contract from the Hull Corporation for the construction and laying of electric mains in the streets in the area prescribed by the Provisional Order. The work will be commenced at once, Mr. B. H. Jenkinson, who has recently completed the Southampton work, having the management of the contract on Messrs. Crompton and Co.'s behalf. The tender amounts to about £8,000.

——— The following tenders have recently been accepted for the Glasgow lighting work:—

Half-inch insulated cables and triple potential leads—W. T. Henley's Telegraph Works Company (Limited).
Quarter-inch insulated cables—India Rubber, Gutta Percha, and Telegraph Works Company (Limited).
Copper-strip—Elliot's Metal Company (Limited).
Excavating trenches and laying electrical conductors—Mr. W. Pollok.
Insulators—Messrs. Stiff and Sons.
Storage cells—Crompton-Howell Electrical Storage Co. (Limited).

THE ELECTRIC LIGHTING OF KILLARNEY.—The contract for the execution of this work has been obtained by the Brush Electrical Engineering Company (Limited). It is proposed to replace the 2,000 gaslights in use in the town with incandescent lamps, and the public lights with arc lamps. For this purpose £6 per Cent. Debentures of £10 each to the amount of £3,000 are to be issued. Underground mains will be used. Mr. Charles E. Leahy, Tralee, has negotiated the contract, which, the *Cork Examiner* learns, has been concluded on very favourable terms.

SALES BY AUCTION.—Messrs. Wheatley Kirk, Price, and Goulty announce in our advertisement columns that they will sell by public auction, on Tuesday next, the 24th inst., the valuable freehold land and buildings known as the St. James' Iron Works, St. James' End, Northampton, lately in the occupation of Messrs. Allchin, Linnell, and Co.; and on the three following days the entire contents of these works, comprising the modern plant and machinery, the stock of new engines, boilers, and agricultural and other machinery, and the engineering stores. Further particulars and catalogues may be obtained from the Auctioneers, 49, Queen Victoria-street, E.C.

SOUTH OF ENGLAND TELEPHONE COMPANY (LIMITED).—A meeting of the members of this Company is to be held at 5, Moorgate-street, E.C., on June 9th, at 2 p.m., for the purpose of receiving an account of the winding-up.

NEW PORTABLE ELECTRIC LAMP AND POWER SYNDICATE (LIMITED).—A meeting of the members of this Company (in voluntary liquidation) will be held at 11, Abchurch-lane, E.C., on June 22nd, at 12, to receive the liquidator's accounts.

MESSRS. KING, MENDHAM AND CO.—This firm have appointed Mr. W. B. Allison, 12, Fenchurch-st., E.C., their sole London agent.

THEATRE VENTILATION.—The ventilation of the theatre in the Musical and Dramatic Exhibition at Vienna has been carried out by the Blackman Ventilating Company (Limited), of 63, Fore-street, E.C., by means of a Blackman fan 72in. in diameter, driven by belt from a motor, and blowing in fresh air under all parts of the ground floor. The impure air is removed by eight electric Blackmans, distributed in various parts of the house. The current driving these fans is at a pressure of 150 volts, and at the opening of the Exhibition on Saturday last the Company's engineer (and the inventor of the electric Blackman) was presented to the Emperor during his inspection of the building.

COUNTRY HOUSE LIGHTING.—Rookwood, Llandaff, the residence of Sir Edward Hill, K.C.B., M.P., is being fitted by Messrs. Drake and Gorham for lighting throughout with electricity. A 7 H.P. gas engine will drive an 8-kilowatt dynamo, and power will be transmitted a considerable distance for actuating a pump.

MESSRS. POOLE AND WHITE (LIMITED).—Mr. T. G. Poole has resigned his position as Managing Director and Secretary of Poole and White (Limited), but retains his interest inthe Company.

ROYAL MILITARY TOURNAMENT.—The electric lighting of the Royal box and the officers' quarters and offices at this popular show has been carried out by Messrs. Woodhouse and Rawson United (Limited), Epstein accumulators of the "country house or private installation" type being used as a reserve. Two balloon lights, and also "Scott's Signalling Lantern" by which the Morse signals are flashed, have also been provided by this Company. The whole of the work was carried out in three days.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

April 30, 1892.

8,165. F. V. ANDERSEN. Catford. Improvements in electric meters.

8,196. B. DEAKIN and W. L. SPENCE. Manchester. Improvements in arc light poles or masts.

8,211. M. H. SMITH and T. P. WILSON. London. Improved means for stopping or controlling electrical railway and tramway engines or carriages.

8,212. M. H. SMITH and T. P. WILSON. London. Improved means of holding and supporting electric conductors or otherwise, ropes or bars.

8,213. M. H. SMITH and T. P. WILSON. London. Improvements in coupling electric conductors and like wires.

8,222. W. C. RECHNIEWSKI. Paris. Improvements in dynamo-electric machines and motors. [Date applied for under Patents Act, 1883, sec. 103, October 31, 1891, being date of application in France].

May 2, 1892.

8,242. F. A. HASELWANDER. Manchester. Improvements in and connected with electrically propelled vehicles.

8,258. M. H. SMITH and T. P. WILSON. London. Improvements in carrying or supporting electric collectors.

8,265. W. H. INGALL. London. An improved globe or shade holder for electric, gas, or other lamps.

8,267. F. T. HOLLINS. Leytonstone. Improvements in electrical circuit arrangements and apparatus for telegraph message signalling.

8,268. G. S. GRIMSTON and A. H. DYKES. London. Electrical steering gear.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

6,485. GRAVIER. Dynamo-electric, &c. machines.

6,730. MORDEY. Dynamo-electric machines.

8,323. GOLDSMID. (Riatti). Thermo-electric apparatus.

9,291. BISHOP. Electric arc lamps.

9,734. ALDRED. Dynamo-electric machines.

10,082. JABLOCHKOFF. Voltaic batteries.

10,256. KING AND MENDHAM. Electric bells.

20,864. HODGKINSON AND THOMPSITT. Electro-medical coil and battery.

1892.

871. LAKE. (Brooks). Electric cables.

4,764. LAKE. (Hammond). Electric wire insulators.

4,773. REDFERN. (Bergmann). Electrical conductors.

4,816. FAIRWEATHER. (Phillips). Electrical cables.

4,961. MUIRHEAD. Electrical slide resistances.

5,096. SILKMAN. Printing telegraphs.

COMPANIES' MEETINGS.

West India and Panama Telegraph Company (Ltd.).

The thirtieth ordinary general meeting of the members of this Company was held at Winchester House, Old Broad-street, on Tuesday; Mr. C. W. Earle in the chair.

The SECRETARY (Mr. R. T. Brown) read the notice convening the meeting and the minutes of the last meeting, which were signed as correctly entered.

The CHAIRMAN then said: Gentlemen, before dealing with the business proper of this meeting it is my painful duty to announce to you that one of those whose names are on the list of this report as a Director of this Company, is now no more. Our esteemed colleague, Mr. William Ford, died on Saturday last. He was present at the meeting which settled this report on the 4th inst., and he was then in his customary health and in possession of his usual mental vigour and spirits. We little thought then that we were seeing him for the last time. Mr. Ford has been very closely connected with this Company, not only as a Director, but also before he was a Director, for he was Chairman of the committee of shareholders which was appointed in 1873 to inquire into the then position of the Company; and it was on the recommendation of that committee that this Board was formed in the beginning of 1874. Since that time, now nearly 18½ years ago, Mr. Ford has continued, without intermission, to take an active part in the administration of your affairs. His keen and trained intellect, combined with his legal knowledge, made him a very valuable adviser to the Board on many intricate questions, while his high personal character and cheering influence in the face of difficulty secured for him the esteem and regard of us all. His death is a very great loss to the Company, and to his comrades on the Board a source of very sincere personal sorrow. I presume, gentlemen, that you will, as usual, take the report as read. I do not think that any shareholder who was present at the last general meeting in November, or who had read the report presented to that meeting, can have been surprised at the result of the half-year's working which we lay before you to-day. Both in that report and at that meeting full prominence was given to the serious effect upon our revenue that was being produced by the—we may say—unjustifiable competition that had been established in the French Islands of Martinique and Guadaloupe in our system; and when I use the term "unjustifiable," in speaking of this competition, I refer to the conditions of the telegraphic business of the field which the French Company have elected to invade. We who have carried on the telegraphic service of that field for some 22 years know how insufficient the telegraphic requirements of that region are to maintain one Company in even fair prosperity. Those requirements have been fulfilled practically at the cost of the shareholders of this Company, for they have never received anything approaching to a fair return on the capital invested in the enterprise. The only consolation I can express for the present circumstances—and it is but a poor one—is that our French rivals are suffering more from this competition which they have concocted than we are. Their traffic from Guadaloupe and Martinique we know must be very small, and they do not get it all even in those two French islands, where we are in active competition with them; and when you look further down the line to Paramaribo and Cayenne they have stations which are very unproductive indeed. In the Brazils we know that their traffic has hitherto been quite insignificant, and how they can pay their working expenses with the revenue they have apparently at their command, I am at a loss to state.

A SHAREHOLDER: Do they have a subsidy from the French Government?

The CHAIRMAN: Not from the French Government, but they get it from some of the Colonies. Turning now to the revenue account for the half-year, there is, as usual, but very little scope for remark with respect to the items on the debit side over which the Board have any control, The expenses under Abstract A. show an increase of £62, almost entirely attributable to some additional legal expenses over cable contracts and some additions to postal and stationery account. Under the head of Abstract B., there is a diminution from various causes of £546. There is a very satisfactory omission from among the debit items in that abstract, and that is that there is no charge this half-year for the hire of sloops during interruptions of cables. This is the first time, I think, that we have presented you an account without a charge under that head, and it is also the first half that I can remember in which we have received our subsidies in full—that they have not been subtracted from on account of interruptions. The fact is that during the half-year there has been no interruption at any station of the communications. On balance there is a diminution of expenditure under Abstracts A. and B. in comparison with that of the corresponding period of 1890, of £484. Abstract C., however, is not so satisfactory. It must be remembered, however, that we compare with an exceedingly low account in the preceding year—only £9,155—and also that the cost of cable since that time has increased by about 50 per cent. We have had a good many heavy repairs during the period of the report, but I find that the cost of repairs charged to revenue in the year 1891 does not exceed—is rather below—the average of the cost of repairs for the past ten years, although cables are so much more expensive now than they were. I may tell you that the average cost of our cable repairs charged to revenue in the last ten years has been £26,174 per annum, while for the year 1891 the costs were £24,900; so we are below the average, although in this second half-year it seems rather a serious increase. The sum of £2,119, which has been charged to reserve, represents the cost of renewing a considerable length of the St. Croix-Ponce cable. We have always charged these renewals of long lengths of cable to reserve, and on the present occasion we have followed that precedent. The laying of the new cable between Trinidad and Demerara completes our duplications, I hope. We have already had some advantage out of this, for the old Demerara cable has interrupted during the half-year recently, but owing to the duplicate connection the communication was kept up. I hope now that we may rest from further duplications, for there is no part of our system that we think requires duplications. I wish I could say we can rest and be thankful, but I am afraid that the thankfulness part will not be permanent. I am happy to say that we issued our £30,000 of debentures without incurring any expense for commission or discount, and the cost of the operation was confined to the legal and stamp expenses, printing, and other sundries which will appear in the next account. At our last meeting we were somewhat buoyed up with the hope that the sugar crop of the West Indies was going to be very flourishing this year, but I am sorry to say that that has turned out rather disappointing. The weather in the principal sugar-growing Colonies has not been propitious, and I am afraid that our West Indian friends are not having a good time of it. That re-acts to a certain extent on us. We may, at the same time, hope for a gradual increase in the amount of business we do on account of the reductions, though I am not very sanguine on that point. Hitherto reductions in the tariffs have been followed by a decrease in the number of words sent; and it appears to me that in countries like the West Indies, where you have got a very limited number of the population who employ the telegraph at all the reductions, no matter how great they may be, will not be productive of any great increase in the number of words sent. It is only the leading merchants there who employ the telegraph. You have not a population of the Anglo-Saxon race, which is constantly rising into positions where the telegraph is used. I now propose—

"*That the Directors' report and accounts to the 31st of December, 1891, submitted to this meeting, be and the same are hereby received and adopted; and that, as recommended by the Board, a payment of 6s. per share on the first preference shares, 6s. per share on the second preference shares, and 6d. per share on the ordinary shares, be and the same is hereby declared.*"

Digitized by Google

Sir JAMES ANDERSON: It is my duty to second the motion, and I cannot do less than add my testimony to the words which have fallen from the Chairman respecting the loss of our colleague. I think you all know that in Mr. Ford we have lost a man who did not spare himself or his time in promoting the welfare of the Company; while his legal knowledge was also at our disposal, and we could rely on a man of much intellect and thorough knowledge of legal business to give us his advice on all matters that came before him. We have lost not only a man we esteemed as a friend, but a colleague of great value to this Company; and his death is a great loss to the Directors. I am extremely sorry that it has fallen to my lot for the second time to second this report in the absence of Mr. Ford, who has now gone from us for ever. Nevertheless, we must carry on the business, and I simply and formally second the resolution.

The CHAIRMAN: Does any gentleman wish to ask any questions? If not, I will put the question. He then submitted the resolution in the usual manner, and having declared it carried unanimously, said: The next resolution I have to propose is—

"*That Henry Holmes, Esq., be and he is hereby re-elected a Director of the Company.*"

Mr. WILLIAM ANDREWS: I will second that.

The motion was carried.

The CHAIRMAN: I now have to propose—

"*That Henry Weaver, Esq., be and he is hereby re-elected a Director of the Company.*"

Mr. GEORGE VON CHAUVIN seconded the motion, which was carried.

The CHAIRMAN: The next resolution relates to the re-election of the auditor, and that will come from the other side of the table.

Mr. JOHN NEWTON proposed the re-election of Mr. John George Griffiths as auditor for the ensuing year.

Mr. W. GRIFFITH seconded the resolution, which was carried.

The CHAIRMAN: That, gentlemen, concludes the business of the day, and I am obliged to you for your attendance.

Mr. JOHN NEWTON: I beg to propose a vote of thanks to the Chairman and Directors, and in doing so I wish to express my deep sympathy with them for the loss which they and the Company have sustained in the death of Mr. Ford. I happen to have been a shareholder from the commencement of his services. I well remember the time that he was appointed, and he was always an energetic and fearless advocate of the shareholders' rights. I think that an event of this kind should not pass by without some expression of sympathy on our part with his family.

Mr. HARKER seconded the motion, which was unanimously adopted.

The CHAIRMAN: We have already passed a resolution at our Board expressive of the sympathy and regret we feel at our sad loss in Mr. Ford's death, but I will take care to incorporate the feelings of the shareholders which Mr. Newton has so kindly expressed. We are much obliged to you.

The proceedings then terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

AGRICULTURAL MACHINERY COMPANY OF FRANCE (LIMITED).—Among the objects of the above named Company, which was registered on May 13th, with a capital of £80,000, in £5 shares, to acquire and carry on the business of agricultural machinery merchants, carried on by H. Thiot and Co., at Paris, Marseilles, Bordeaux, and elsewhere, is included that of carrying on the business of mechanical and electrical engineers, and also that of constructing, improving, maintaining, working, and turning to account telegraphs, telephones, electric light, heat, and power supply workers, railways, tramways, &c.

BICKLE AND CO. (LIMITED).—This Company was registered on May 13, with a capital of £50,000, divided into 4,950 ordinary and 50 founders' shares of £10 each. The objects are to acquire the business of Bickle and Co., mechanical engineers, and to carry on the business of an electrical company in all its branches, and particularly to carry on the business of electricians, electrical contractors, electrical engineers, suppliers of electricity for all purposes, and manufacturers, and hirers of and dealers in all apparatus and things required for, or capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity.

LONDON AND HAMPSTEAD BATTERY COMPANY (LIMITED).—This Company was registered on May 13, 1892, with a capital of £50,000, divided into 7,000 preference and 3,000 deferred shares of £5 each. The objects are to acquire and take over as a going concern the business of electrician and otherwise carried on by Mr. Alfred W. Armstrong at Finchley-road, and in the parish of St. John's, Hampstead; to carry on in the parish of St. John's, Hampstead, and elsewhere, the business of an electric light, electric storage, or electric power supply company in all or any of its branches, and also the business of electricians, mechanical and electrical engineers, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of and dealers in all appliances, apparatus, and things required for or capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity. The number of Directors is not to be less than three nor more than seven, the first being William C. Hallett, Robert J. S. Beeton, and Alfred W. Armstrong.

LONDON REAL PROPERTY AGENCY (LIMITED).—Among the objects of this Company, which was registered on May 13th, with a capital of £50,000, divided into 3,000 ordinary and 2,000 founders' shares of £10 each, is included that of constructing, maintaining, improving, developing, working and managing waterworks, gasworks, electric power, heat, and light supply works, telephone works, &c.

R. C. CUTTING, DOUGLAS AND CO. (LIMITED).—This Company was registered on May 11th, with a capital of £20,000, in £5 shares (with power to increase the same). The objects are to acquire the goodwill, plant, trade marks, and stock in trade and to carry on the business of Messrs. R. C. Cutting, Douglas and Co., lightning conductor manufacturers and electrical engineers, of Doctors' Commons, London, E.C., and to carry on any other business which may seem to the Company, directly or indirectly, to enhance the value of, or render profitable, any of the Company's property or rights.

ATLAS ELECTRIC APPLIANCES COMPANY (LIMITED).—A general meeting of the above-named Company was recently called at the offices of the liquidator, 10, Coleman-street, E.C., for the purpose of receiving the final report of the winding up, dated February 24, 1892; but there was no quorum, and therefore no business could be transacted.

GALLOWAYS (LIMITED).—The annual return of the above-named Company, made up to March 2nd, was filed on March 4th. At the time of making up, 2,108 shares had been taken up, and according to the return, the full amount has been called up on each, and the full amount £210,800 paid.

LLANELLY ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 9, 1891, was filed on March 15, 1892. The Company was registered on October 26, 1889, with a capital of £15,000, divided into 10 "A" and 14,990 "B" shares of £1 each. At the time of the making up, 7 "A" shares had been taken up, upon which nothing had been called or paid.

ST. PAUL'S PRINTING AND PUBLISHING COMPANY (LIMITED).—The statutory return of this Company, made up to May 13th, was filed on the same day. At the time of making up, 1,704 shares had been taken up, and 10s. per share had been called, resulting in the payment of £650, and leaving £202 in arrears. Among the principal shareholders are:—Robert Kaye Gray, civil engineer, of Lessness-park, Abbey Wood (500); Henry Alabaster, publisher, engineer and journalist, of 14, Therapia-road, Honor Oak (200); T. Ernest Alabaster, publisher, engineer and journalist, of 60, Gresham-road, S.W. (200); and Harry R. Kempe, engineer-in-chief G.P.O. (200).

SYNDICATE OF ELECTRICAL ENGINEERS (LIMITED).—The annual return of the above-named Company, made up to May 14, 1891, was filed on April 30, 1892. The Company was registered on December 31, 1889, with a capital of £10,000, divided in 1,900 ordinary and 100 founders' shares of £5 each. At the time of making up (May 14, 1891), 1,007 ordinary and 74 founders' shares had been taken up. £2 per share had been called on the ordinary shares, resulting in the payment of £1,903. 10s. and leaving £110. 10s. unpaid. By an agreement with Robert Hammond it was agreed that he should pay all the costs of forming and registering the Company, and in consideration thereof the 100 founders' shares were issued to him as fully paid.

W. T. HENLEY'S TELEGRAPH WORKS COMPANY (LIMITED).—The annual return of the above-named Company, made up to April 7, 1892, was filed on April 12th. The Company was registered on February 21, 1880, with a capital of £70,000 in £100 shares. By special resolutions the shares of £100 each have been divided into 10 shares of £10 each, and the capital has been raised to £100,000 by the creation of 3,000 preference shares, bearing a fixed cumulative dividend at the rate of 7 per cent. per annum. . At the time of making up, 6,727 ordinary and 2,092 £7 per cent. preference shares had been taken up, and the full amount called, resulting in the payment of £83,330, and leaving £4,860 in arrears upon preference shares.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended May 15th were £709, as against £665 for the corresponding period of last year, being an increase of £44. The total receipts to date, from January 1st last, amount to £15,930, against £14,607 in the corresponding period of 1891, being an increase of £1,323.

COMPAGNIE CONTINENTALE EDISON.—The report of the Directors presented at the annual meeting recently held in Paris disclosed a favourable state of business as regards the supply of light, they having installed, up to March 31, 1892, a total of 43,942 10-c.p. lamps, as against 29,782 at the same period of 1891. The sale of the apparatus constructed at their works at Ivry had not, however, developed as much as was hoped. The accounts showed a net profit of 425,396fr., and a dividend was declared of 20fr. per share, absorbing 400,000fr.

ELMORE'S METALL-AKTIEN-GESELLSCHAFT.—This is the title of a Company just registered in Germany, and seems to indicate that the Elmore group is desirous of offering to the German public a share in the future good things which are in store for us. There is, however, nothing in the notice which appears in the *Electrotechnisches Echo* to indicate whether the above Company is affiliated with Elmore's German and Austro-Hungarian Metal Company (Limited).

REUTER'S TELEGRAM COMPANY (LIMITED).—The twenty-eighth ordinary general meeting of the shareholders of this Company will be held on Wednesday, the 1st prox., at noon precisely, at the Company's offices, No. 24, Old Jewry, London. The transfer books of the Company will be closed from the 17th until the 31st inst. inclusive.

Digitized by Google

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the fortnight ended May 15, 1892, amounted to £2,666, as compared with £3,155 in the corresponding period of last year, a decrease of £489.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—**The traffic receipts for the week** ended May 13, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,635.

A CORRECTION.—At the meeting of the Chelsea Electricity Supply Company, the report of which appeared in our last issue, the Chairman, in the course of his remarks, referred to 2½ years' experience, and not to 2 years' experience.

CRICKET.—EASTERN TELEGRAPH COMPANY'S HEAD OFFICE STAFF v. OFFICERS OF THE CABLE STEAMER, "JOHN PENDER."—This match was played at West Brompton on Friday, the 13th inst., and resulted in an easy win for the Head Office Staff. The "Sailors" went in first, and knocked up 37, the highest score being obtained by Chief Engineer Corns, 9. The Head Office Staff scored 108, the highest individual score being Burke (b Bonitto) 28. In their second innings the "Pender's" team fared badly, scoring only 16, of which Drake made 12. The bowling of the "Staff" was very formidable. In the first innings J. G. Macmillan captured six wickets for 11 runs, and in the second S. Wells took eight for 8. On behalf of the "Pender," Bonitto was very successful, taking six for 33 runs. In the result the "Land Lubbers" won by an innings and 55 runs. Mr. G. C. Jack captained the home team and Mr. Bonitto the "Sailors."

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 732.—Vol. XXIX. FRIDAY, MAY 27, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

Although an official imprimatur does not, as yet, in this country carry quite so much weight with the public as is the case on the Continent, electric traction has certainly won a point by the Report of the Joint Committee of Lords and Commons, which will be found elsewhere in the present issue.

With regard to the all important question of the size of tunnel, it is stated that "the evidence submitted to the Committee on the question of the diameter of the underground tubes containing the railways has been distinctly in favour of a minimum diameter of 11ft. 6in.;" from which we gather that the Committee think the tunnels ought not to be smaller, but see no particular reason why they should be bigger. They rightly point out, in paragraphs 4-8, that, with the exception of the Great Northern and City Railway, the proposed lines are in reality only *street* railways, as our Americans term them. We admit the full force of this argument, but, nevertheless, regret that the Committee did not consider the future. Steam railways were so utterly unlike anything that had preceded them that want of prescience was excusable, and the laying down of lines on half-a-dozen different gauges a venial error. But this does not hold good for 1892.

As to the increase in first cost which the adoption of 16ft. tunnels would entail, Sir Douglas Fox's estimate for them is £650,000 per mile, a figure which compares favourably with the million a mile of the Inner Circle. Again, as Mr. Wolfe Barry pointed out, a railway able to carry all the traffic of the country is double the value of one which can only carry strictly urban traffic. However, if the promoters of these schemes do not see matters in this light, and if it is really a choice between small tubes or none at all, by all means let the tubes be small. The example of the Great Northern Railway will, in all probability, soon be followed, and the lines for which we are contending will be built by the existing railway companies instead of by the present pioneers; that will be the only difference.

While the usual Ministerial State dinners were being given in celebration of Her Majesty's birthday on Wednesday last, a less formal and probably more agreeable evening was spent at the Crystal Palace by members of the Whitehall Club and their guests. Special experiments were provided in the afternoon at the side shows. Messrs. Swinburne & Co. ran a current under a pressure of about 100,000 volts through a large roofing slate from corner to corner; the current was then transformed down to a pressure of about 80 volts, and was used to run an arc lamp and a self-starting motor. Messrs. Siemens Bros. showed the glowing of a long vacuum tube without wires, and one or two other Tesla experiments. During the dinner, between 70 and 80 cutlets and about 40 pancakes were cooked on electrically heated frying-pans, and coffee was also made.

It is remarkable that, until these demonstrations of the domestic application of electric currents, little or nothing has been done in this direction since the Crystal Palace Electrical Exhibition of 1882. Lane Fox then showed his egg-boilers and coffee-pots, and the cooking is being done at the present Exhibition exactly on his system with enamelled wires. We recently gave some calculations of the expenditure of energy required, and took the case of boiling a pint of water. It has, however, been pointed out to us that to boil water is one of the stiffest tasks that can be set. This is no doubt the case, since nothing has a higher specific heat than water.

It ought to be better known that the cooking pans and flat-irons which have attracted so much attention can be used on an ordinary lamp circuit. An iron takes about four amperes when cold, and the current soon drops when the metal warms up. A wire of No. 18 gauge is often used for single lamps, and most wiring rules prohibit smaller sizes. We think that for mechanical reasons No. 18 is too small, and a larger size, or 3/22, ought to be employed. The sectional area of No. 18 S.W.G. is practically the same as that of 3/22, and the diameter is 0·048in. Mr. Kennelly found that it took 5 amperes to raise a wire of 0·043in. diameter insulated and enclosed in ordinary wooden casing, 18° Fahr.; it is not, therefore, necessary to alter the wiring of a house to enable these useful applications to be employed.

It was satisfactory to hear from Mr. A. R. Bennett on the occasion of the press gathering on Wednesday last, at 110, Cannon-street, that the New Telephone Company is really about to proceed from promise to performance. One month's canvass has, it was stated, resulted in more than 2,500 adherents, and London is shortly to enjoy all the blessings of the Mann system of switching, twin underground wires, double-pole Bell receivers, and Johnson transmitters. Whether the

Digitized by Google

New Company's spirited attack upon the National Company's metropolitan stronghold will meet with the financial reward it deserves, is a matter which the advisers of the venture have doubtless thoroughly weighed before embarking in the enterprise; for our own part we cannot confess to very sanguine anticipations on this point. This much may be predicted. The manifold inconveniences of two competing telephone companies will soon cause the public to make up its mind to support one or the other in a thoroughly effective manner, and when that determination is arrived at, either the New or the National Company will have to promptly make peace with its antagonist on the best terms it can. It will be a Six Weeks' rather than a Six Years' war.

As far as mere electrical equipment is concerned, the New Telephone Company will make a good start. Complete metallic circuits and underground wires are in themselves a sufficient recommendation; and, whatever may be urged against it, there can be but little doubt that the Mann system, in doing away with two distinct operations on the part of the operator, should result in increased celerity in connecting subscribers. The Johnson transmitter again is an improvement upon the Blake, which frequently gets out of adjustment when most wanted. The Johnson transmitter, we may mention, is much the same as the Binswanger-Coates microphone described in our issue of September 4, 1891. Finally, if there be a better receiver than the plain Bell, it is probably the double-pole Bell.

At an inquest held on the deaths resulting from a fire in the Haymarket, a consulting engineer made, what is called in Police courts, "a rambling statement," full of surmises and possibilities, but devoid of facts or anything that could be called evidence. He discovered that some wires were run under plaster near some gas pipes, and understood that the building was insured in the Phœnix office; but he was sure that their inspector would not have tolerated the position of them if he had known their proximity to the gas pipes. We understand that only a very small portion of the insurance was effected quite recently with the Phœnix office, and that it had not been inspected. The public are now well aware that there is no danger whatever if the wiring is properly done, and that the inspection by the officers of the Fire Insurance Companies and the conditions of the Supply Companies are quite sufficient to ensure perfect safety. The fact that no fire has ever occurred from electric lighting where the wiring has been carried out with what is to-day considered ordinary care, is in itself a proof of the absence of danger. A few fires have occurred, and all of these have been distinctly traced to ignorant work. Confidence in electric lighting is now sufficiently well established to be unshaken by such vague guesses as were presented at this inquest.

The Coroner gave it as his opinion that "danger of fire from an installation of the electric light appeared to be greater than in the case of an escape of gas;" but displayed his entire ignorance of the matter by saying that "it was to be regretted that there were no set rules for the performance of the work." This, when Codex Heaphæ has reached its nineteenth edition, to say nothing of the joint Fire Risk Rules of the twenty-five leading companies, the regulations of eight supply companies, and those of the Institution of Electrical Engineers, besides the specifications both of contractors and of consulting engineers!

Electricity seems destined to afford lawyers of all lands an opportunity of showing their professional skill at splitting hairs. In America several legal questions have cropped up. Is electricity dutiable? Can it be stolen? In France it was a moot point until a short time ago whether an electricity supply Company was a Société Civile or a Société Commerciale, a matter of no little importance to investors, who in the latter case would only be liable for the amount of their shares. A Société Commerciale, it appears, is one which has for its principal object "the accomplishment of acts of commerce," such as buying raw material and reselling it at a profit, manufactured, or in its natural state. The Edison Company of Saint Etienne, summoned before the Tribunal of Commerce of that town by one of its customers, declined to submit to the jurisdiction of the Court on the ground that the supply of electricity from a central station did not constitute a commercial act, "the company only sold a product which it gathered from nature, and which was a *res nullius*." The Tribunal of Commerce, nevertheless, declared itself competent to try the case, and on appeal its decision was upheld; so that in France, at any rate, electricity when supplied from a central station must be deemed a manufactured article. Across the Atlantic, where the manufacturing interest is dealt with very tenderly by the tax gatherer, a similar decision would add appreciably to the profits of central stations.

Crystal Palace Electrical Exhibition.—It has been decided to close this Exhibition on Saturday, July 2nd.

Damage by Lightning.—An assistant at the Cape Observatory was struck by lightning while attending to the rain gauge, and severely injured.

The Frankfort Exhibition.—The publication of the Official Report on the Exhibition and of the Official Report of the Jury is postponed until the end of the summer.

Birthday Honours.—Among the gentlemen created K.C.B. on the occasion of Her Majesty's birthday was Mr. Courtenay Boyle, Assistant Secretary to the Board of Trade.

Charlottenburg.—According to the *Charlottenburg Zeitung* Messrs. Siemens and Halske have obtained a concession for an electric tramway between Charlottenburg and Berlin.

Panama.—According to *El Telegrafo Español*, an electric tramway is to be constructed in Panama. Several central stations are to supply current for the 30 H.P. motors to be used. The latter, it is said, are being built by Messrs. Siemens Brothers.

Copper.—Negotiations between the European and American Companies progress favourably, says *The Statist*. The negotiations contemplate a restriction of the output, but not such as would greatly enhance the value of copper, or in any way inconvenience consumers. A very friendly spirit is evinced by all parties.

The Electrical Trade Union.—On Thursday last week a meeting of men engaged in the electrical trades in Leeds was held. It was stated that the Leeds branch has only been established about twelve months, and numbers 61 out of a constituency of

Digitized by Google

about 100, and within three months of the formation of the union the wages of the men were raised 5s. per week all round.

Glasgow.—Last week the Deputy Town Clerk was summoned to the Central Police Court on a charge of allowing black smoke to issue from the furnaces at the electric lighting station in John-street. In imposing a fine of 40s., the magistrate remarked that the Corporation, who were endeavouring to have the penalties for smoke nuisances increased, should be the first to set an example to others.

Electrical Bills in Parliament.—The following Bills were read a second time in the House of Commons on Monday:—Liverpool Overhead Railway Bill, Baker-street and Waterloo Railway Bill, Great Northern and City Railway Bill, Hampstead, St. Pancras, and Charing Cross Railway Bill, and Waterloo and City Railway Bill. On Wednesday the Central London Railway Bill and City and South London Railway Bill were read a second time.

Electric Lighting of the Theatre and Hall in Vienna.—For the electric lighting of the theatre and hall in Vienna, which was started on 7th inst., 1,200 H.P. are being used. The work has been carried out by Messrs. Siemens and Halske. The dynamos are driven by six 200 H.P. engines built by the Maschinenfabrik Waniek, and steam is supplied by tubular boilers by Messrs. Simonis and Lanz, having a total heating surface of 13,500 square feet.

The Metropolitan Electric Railway Schemes.—The Baker-street and Waterloo; Great Northern and City; Hampstead, St. Pancras and Charing Cross; Waterloo and City; Central London; and City and South London Railway Bills, have been referred to a Select Committee of the House of Commons, consisting of Sir John Kennaway (Chairman), Mr. Esslemont, Mr. T. W. Sidebotham, and Mr. E. Holden. The first meeting of the Committee will be held on Tuesday next, at 11:30.

The Faure Patent in Germany.—We are informed that the Supreme Court of Appeal at Leipsig has just delivered a judgment confirming the decision of the Patent Office at Berlin, and establishing the validity of the Faure Patent. Several of the secondary battery manufacturers in Germany had entered process in the Patent Office, seeking to have the Faure Patent declared invalid on the ground that its main features had been anticipated. This contention has now been finally disposed of in favour of the Faure Patent.

Chicago Exhibition.—To enable visitors to the Machinery Hall to pass from one end of the building to the other at an elevation, and thus gain a birdseye view of the exhibits, three large electric travelling cranes will be constructed, each with a lifting and carrying capacity of 20 tons. Previous to the opening of the Exhibition these cranes will be used for the moving of heavy exhibits; afterwards they will be covered with broad platforms capable of carrying several hundred people at each trip.

The Best Frequency for Alternating Currents.—Having regard to all the circumstances of the case, says *Industries*, we believe the American frequency of 130 is about the right one, and that low limits, such as 40 or 60, are a mistake. Recently we have seen 20 periods per second proposed. This would be ruinous both to the pocket and to the eyesight. Helmholtz found that the eye could distinguish 25 periods per second. This low frequency would probably be unworkable in the dynamos, motors, and especially in the transformers.

The Electric Arc.—In the course of some insurance litigation before an American Court relative to liabilities of insurance companies at the destruction of an electric light station, one of the experts, says *Engineering*, took the position that an electric arc was not a flame, because it was not in any way dependent upon the air or other chemical support, and could be maintained *in vacuo*, and therefore the damage done by the arc did not come within the liability of the underwriters, although they accepted liability for the measure of damage caused by fire resulting from the arc, yet the portion of damage caused by melting of the apparatus by the arc was not included in that damage.

Manchester.—Mr. S. J. Smith, one of the Inspectors of the Local Government Board, held an inquiry last week into the application of the Town Council to borrow the sum of £150,000 for purposes of electric lighting. Sir John Harwood, who was called upon to give evidence, said the Corporation had had the question of electric lighting under consideration for the last ten years at least. He thought that the money now applied for was little enough, and that it would have been better to borrow £200,000. The contracts which had been already let and others which would be let shortly amounted to £78,000. Dr. John Hopkinson, who was next called, said that the best system under the circumstances was the five-wire system. The inquiry then closed.

Train Lighting.—The Brush Electrical Engineering Corporation showed a train-lighting dynamo in operation at their Lambeth Works on Friday last. A Brush machine was used, and was arranged for driving from the axle of a guard's van. The commutator was filled up flush with mica, to allow butt brushes of wire gauze to be used. A centrifugal governor was connected to the brushes by a system of levers, which we were unable to examine, as they were enclosed in a box; the effect was to rock the brushes over, to keep the volts constant. Relays, automatic switches, and resistance coils are used for exciting the fields, charging accumulators, and for running the lamps direct, on a system worked out mainly by Mr. Houghton, of the Brighton and South Coast Railway.

Electric Traction on the Baltimore and Ohio Railroad.—The Thomson-Houston Company has offered, and the Baltimore and Ohio Company has accepted the offer to run the trains in the Belt tunnel under Baltimore by means of electricity. Eighty-ton locomotives, with armatures direct on the axle, will be employed. The Thomson-Houston Company guarantees that its plant and system shall be successfully installed and operated before it is paid for. The Thomson-Houston Company proposes to guarantee the transportation of goods trains of a maximum weight of 1,300 tons at the rate of fifteen miles up the grade in the tunnel, and passenger trains of one-half that weight at thirty miles an hour. The power of each motor is to be guaranteed as equal to a draw-bar pull of 32,000lbs. There will be four engines in the power house of 700 H.P. each. The plant is to come into operation in December next.

The Albert Medal of the Society of Arts.—The Albert Medal of the Society of Arts for the present year has been awarded to Mr. Thomas Alva Edison, in consideration of the distinguished services rendered by him to the progress of electric lighting, telegraphy, and the telephone. This medal was instituted in 1862 as a memorial of the Prince Consort, for 18 years the President of the Society, and is awarded annually for distinguished merit in promoting arts, manufactures, or commerce. It was first awarded in 1864 to Sir Rowland Hill, and amongst the distinguished men of science who have since received it have been Faraday, Whitworth, Liebig, Lesseps, Bessemer, Siemens, Armstrong, Thomson, Joule, Hofmann, and Helmholtz. In 1887 it was presented to Her Majesty on the occasion of her jubilee. This is the second occasion on which it has been awarded to an American. In 1884 it was given to Captain Eads in recognition principally of his great engineering works at the mouth of the Mississippi.

The Chief Electrician to the Post Office.—On Friday evening last, Mr. Labouchere asked the Postmaster-General whether he was aware that Mr. W. H. Preece was in the habit of taking private practice in electrical work; and whether, in view of the fact that he was a Civil servant in receipt of an annual salary, that was in accordance with the rules of the Civil Service. Sir J. Fergusson said that the case of Mr. Preece was exceptional. Before he entered Her Majesty's service, 22 years ago, he held certain paid employments besides his appointment as engineer of the Electric Telegraph Company. Those employments he relinquished as being incompatible with his appointment at the Post Office; but, with the knowledge of the department, he had continued to advise on great electrical questions outside of his regular duty. His action in this respect had been quite public, and his reports had been published. His official work was by no means confined to office hours. It was performed unsparingly early and late. The case was altogether exceptional, and could not form a precedent.

The Azores Cable.—The Lisbon correspondent of *The Times*, under date May 25, writes:—"A single tender only—namely, the one from the French company—was made this afternoon for the laying of the cable from Lisbon to the Azores. This Company offers to accept all the conditions laid down, together with some pecuniary advantages, to lay cables from the Azores to the Antilles and South America, or from the Azores to Central or North America within three years; and to lay a cable from Fayal to Flores by April, 1893. It has also presented an official letter from the French Government according it the exclusive right during five years to lay cables between France, Portugal, and the French colonies, and another document by which the Government of Hayti accords it the exclusive right for 30 years to land cables on Haytian territory. In reference to their proceedings in these negotiations, I understand that the Portuguese Government yesterday received an expostulation from the British Government. But, notwithstanding the diplomatic intervention of their Government, I understand that the British Company (the Telegraph Construction and Maintenance Company) are disposed to withdraw their protest, and lay the cable to the Azores this summer upon receiving fair treatment from the Portuguese Government."

Lichtenfeld's Electric Railway Signals.—A system of electric signals, invented by Mr. Sigismund Lichtenfeld, is being noticed at some length by the daily press. We recently had an opportunity of examining a model representing a signal cabin and part of a double-track railway. The inventor proposes his system as an addition to those at present in use, and claims that by its means the signal-man would be made aware of the position of a train at short intervals, and could signal from his box to the driver on the locomotive direct. The system is not affected by foggy weather, and the ordinary fog-signals would not be needed. We may say at once that it is a system of signalling by means of electric bells or single needle instruments and indicators. Special insulated rails are laid parallel to the ordinary rails. Underneath the locomotive a suitable contact is fixed. As the locomotive passes over the part of the line where the insulated rails are fixed a battery circuit is completed through the contacts and the ordinary rails as a return circuit, and bells should ring in the signal-box and on the locomotive, and indicators should work. We use the word "should" because such electric connections are so liable to get out of order. We fear that in its present form the invention is inapplicable to most lines, owing to its expense and unreliability.

The Electrical Trade Section.—The annual meeting of the Electrical Trade Section will be held at Botolph House, Eastcheap, at 2.30 p.m. to-day, to consider the appended agenda. A full attendance is particularly requested. *Agenda.*—1. Chairman's report as to the work of the Section since its last annual meeting. 2. Election of chairman and deputy chairman for the ensuing year. 3. To consider the desirability or otherwise of the Section following the precedent of other Sections of the Chamber, in convening the whole of the membership of the Section to all future meetings, appointing special committees to deal with special subjects. 4. The attitude of the electrical trade towards the Chicago Exhibition. 5. Telephone question. 6. The attitude of the Section towards the Parliamentary Committee, who are to consider the whole question of electric railways in London. 7. The action taken by the Chamber in reference to the question of Overhead Wires, and to consider the reply from the President of the Board of Trade. 8. Bye-Laws of the County Council in reference to Overhead Wires. 9. Electrical communication on the coasts. 10. Commercial Education.—To consider whether the Section would be prepared to support the commercial education scheme of the Chamber by subscribing annually for a prize or prizes to be awarded in the name of the Section. 11. Co-operation of the Section with the New Mining Section of the Chamber. 12. Proposed addresses. 13. Other matters.

The National Telephone Company and its Sheffield Subscribers.—An interview took place last week at the offices of the Chamber of Commerce between the Committee appointed by the recent meeting of users of the National Company's telephone system and a deputation of the Directors of the Company. Mr. Gaine stated that the tariff which had caused so much dissatisfaction in Sheffield was based upon the working of the Company's system in Lancashire. He then submitted the new tariff. The new scale of charges was an annual payment of £8 for the use of a wire within a mile and a half radius of the parish church or of any exchange within the free radius; an annual payment of £10 for a two-mile radius; and a payment of £2. 10s. per annum for every half-mile beyond that radius. The charge for private houses would be £7 per annum if they were within the two-mile limit. Mr. Gaine stated that the Company was prepared to enter into a contract with subscribers for any length of time at the proposed new rates. After a lengthy discussion the deputation withdrew, and the Committee proceeded to discuss the new rates. No decision, however, was arrived at. The Committee also had an interview with Mr. A. R. Bennett, who stated the terms on which the New Telephone Company were prepared to come to Sheffield. On Tuesday the Committee again met, and decided that the proposed long-distance charges were excessive. A Sub-Committee was appointed to draw up a report on the negotiations to be presented to the meeting of the subscribers, called for Monday next. It is understood that the National Company will modify the long-distance charges.

The Telephone in Canada.—The following statistics with regard to telephonic activity in the Dominion are culled from the *Canadian Electrical News*, of Toronto. By comparing these statistics with those of other countries it will be seen, says our Toronto contemporary, that we occupy an enviable position, both as regards the extent and efficiency of our telephone service, and the moderateness of the price at which it is furnished. The telephone rentals charged in some of the principal cities of the United States are as follows:—

New York	£48
Boston	40
Chicago	25
Philadelphia	20
St. Louis	20
Cincinnati	20
Buffalo	10 and 2½d. per call.
Kansas City	14. 10s.

In Canada the average rate is a little over £6. At Montreal the annual rental amounts to £10, and at Toronto it is £9. As evidence of the popularity of the telephone in Canada, it may be mentioned that 540 telephones are in use per 100,000 inhabitants, as against 350 for the United States and 167 for the United Kingdom. Again, in Montreal, there are 25 instruments per 1,000 inhabitants, against 17 in Berlin, 5 in Vienna, 4·2 in Paris, and 1·5 in London. The growth of the Canadian telephone system is shown by the following figures:—

	1880.	1892.
Montreal	312	5,872
Toronto	353	3,965
Hamilton	181	1,160
Quebec	124	1,011
Halifax	87	955
Ottawa	230	942
London	104	805

When the telephone was first introduced, says our contemporary, the public was as anxious to grant facilities as they are to-day prompt to refuse them. At that time it seemed as though every city took pride in having as many poles as possible, and in one notable instance the city gave permission to erect poles in its streets provided they were placed in every street, or, in the words of the contract, "the city shall be fully poled." After alluding to the expensive nature of the telephonic business owing to the continual improvement of apparatus, and the more careful construction rendered necessary by the advent of the "trolley," another very serious source of loss to the companies, remarks the *Electrical News*, is the frequency of sleet storms, which have in many instances totally wrecked their plant and rendered entirely new construction imperative, without any increase of revenue. The storm of March 11, 1892, in Ottawa, caused a loss to the companies, in poles and overhead wires, of probably between £4,000 and £6,000.

ELECTROMAGNETIC THEORY.—XXIX.

BY OLIVER HEAVISIDE.

(*Continued from page 31.*)

§ 135. Deferring temporarily a vectorial proof of the last formula (229), which is the only unproved formula in the connections of the series of circuital vectors, it will now be convenient to bring together the connections of the divergent vectors and associated quantities. We saw the advantage of the systematic arrangement of the connected circuital vectors to be like producing a harmonious chord out of apparently disconnected tones. The advantage is much greater in the divergent series, on account of the less uniform relations involved and the greater need of a system to bring them under rapid mental control. In the circuital series, four kinds of operation were involved; but in the divergent series there are six. The chord will be found to be perfect, though of greater complexity.

Thus, let

$$\mathbf{A}_2, \quad \mathrm{B}_2, \quad \mathbf{C}_2, \quad \mathrm{D}_2, \quad \mathbf{E}_2, \ldots .$$

be a series of vectors and scalars connected as follows:—Start with $\mathbf{A}_2$, which is to be any divergent vector; that is, having no curl. Let B_2 be its divergence; $\mathbf{C}_2$ the slope of B_2; D_2 the divergence of $\mathbf{C}_2$; $\mathbf{E}_2$ the slope of D_2, &c. Then $\mathbf{A}_2$, $\mathbf{C}_2$, $\mathbf{E}_2$, . . . are all divergent vectors. But they are separated from one another by two steps instead of one, as was the case in the circuital series last treated. The intermediate quantities are scalars. Instead, also, of the single operation of curl which suffices, in the circuital series, to carry us from any vector to the following one, we now have two distinct operations; viz., that of slope, when we pass from a scalar to the next vector, as in

$$\mathbf{C}_2 = -\nabla \mathrm{B}_2; \quad . \quad . \quad . \quad . \quad . \quad . \quad (230)$$

and that of divergence, when we pass from a vector to the next scalar, as in

$$\mathrm{D}_2 = \mathrm{div}\, \mathbf{C}_2. \quad . \quad . \quad . \quad . \quad . \quad (231)$$

But if we wish to go down two steps at once, we can do so by means of the Laplacean operator, whether the operand be a scalar, as in

$$-\nabla^2 \mathrm{B}_2 = \mathrm{D}_2, \quad . \quad . \quad . \quad . \quad . \quad (232)$$

or else a vector, as in

$$-\nabla^2 \mathbf{C}_2 = \mathbf{E}_2. \quad . \quad . \quad . \quad . \quad . \quad (233)$$

In this respect, then, we have the same property as in the circuital series.

We have also identity of operation in going up two steps at once, whether from a scalar to the next higher scalar, as in

$$\mathrm{B}_2 = \mathrm{pot}\, \mathrm{D}_2, \quad . \quad . \quad . \quad . \quad . \quad (234)$$

or from a vector to the next higher vector, as in

$$\mathbf{C}_2 = \mathrm{pot}\, \mathbf{E}_2; \quad . \quad . \quad . \quad . \quad . \quad (235)$$

any member of the series being the potential of the second after, as in the circuital series.

Next, to go up one step only, we may utilise the preceding in two ways. First go up two steps and then down one, as in

$$\mathrm{B}_2 = \mathrm{div}\, \mathbf{A}_2 = \mathrm{div}\, \mathrm{pot}\, \mathbf{C}_2, \quad . \quad . \quad . \quad (236)$$

where we pass from the vector $\mathbf{C}_2$ to the scalar B_2 by pot first (up two steps), and then by div (down one step); and also as in

$$\mathbf{C}_2 = -\nabla \mathrm{B}_2 = -\nabla\, \mathrm{pot}\, \mathrm{D}_2, \quad . \quad . \quad . \quad (237)$$

where we pass from the scalar D_2 to the vector $\mathbf{C}_2$ by pot first (up two steps), and then by $-\nabla$ (down one).

Or, secondly, we may first go down one step and then up two, as in

$$\mathrm{B}_2 = \mathrm{pot}\, \mathrm{D}_2 = \mathrm{pot}\, \mathrm{div}\, \mathbf{C}_2, \quad . \quad . \quad . \quad (238)$$

when rising from the vector $\mathbf{C}_2$ to the scalar B_2; or as in

$$\mathbf{C}_2 = \mathrm{pot}\, \mathbf{E}_2 = -\mathrm{pot}\, \nabla \mathrm{D}_2, \quad . \quad . \quad . \quad (239)$$

when rising from the scalar D_2 to the vector $\mathbf{C}_2$.

Finally, if we wish to rise up one step at once, without using the double step either up or down, we can do it by means of

$$\mathbf{C}_2 = (\mathrm{div})^{-1}\, \mathrm{D}_2 = \Sigma \mathbf{r}_1 \mathrm{D}_2 / 4\pi r^2, \quad . \quad (240)$$

when we rise from a scalar D_2 to a vector $\mathbf{C}_2$, which is, in fact, the fundamental formula of the inverse square law upon which our potential investigations are based. But in rising from a vector $\mathbf{C}_2$ to the scalar B_2 just above it in the series, we require to use a different process, namely,

$$\mathrm{B}_2 = (-\nabla)^{-1} \mathbf{C}_2 = -\Sigma \mathbf{r}_1 \mathbf{C}_2 / 4\pi r^2. \quad . \quad . \quad (241)$$

In these formulæ (240), (241), $\mathbf{r}_1$ is a unit vector from the element in the summation towards the place of the resultant; that is, from D_2 to $\mathbf{C}_2$ in (240), and from $\mathbf{C}_2$ to B_2 in (241).

We now have a complete scheme for the divergent vectors as we had before for the circuital series. On comparing them we see that they are alike in the double steps, either up or down, but differ in the single steps. There is but one kind of step up and but one kind down in the circuital series, whereas there are two kinds up and two kinds down in the divergent series. The down step in the circuital series is always done by curl; the up step, shown in (229), may be denoted by $(\mathrm{curl})^{-1}$. In the divergent series the down steps are done by $-\nabla$ and by div; their inverses may be denoted by $(-\nabla)^{-1}$ and $(\mathrm{div})^{-1}$. It is now the nature of these inverse operations (229), (240), and (241) that remains to be elucidated vectorially. The first is the Ampèrian formula rationalized, whereby we rise from electric current to its magnetic force; by the second we rise from (for instance) electrostatic force to the electrostatic potential; or, with a slight change (of sign), from intensity of magnetisation to magnetic potential; in the third we rise from (for instance), electrification to electrostatic displacement.

§ 136. Let p and q be scalar functions, and consider the space-variation of their product. We have

$$\nabla(pq) = p\nabla q + q\nabla p, \quad . \quad . \quad . \quad . \quad (242)$$

a formula not previously used, but which is seen to be true by observing that it is true for each of the three components of ∇. Now integrate through any region. We know that

$$\Sigma \mathbf{N} pq = \Sigma \nabla(pq), \quad . \quad . \quad . \quad . \quad . \quad (243)$$

if $\mathbf{N}$ is the unit normal outwards from the boundary of the region, so that the left member is a surface-summation, whilst the right member is a volume-summation throughout the region bounded by the surface. Equation (243) is, in fact, a case of (157), with pq substituted for p. If, then, the surface-summation vanishes, we shall have a simultaneous evanescence of the right member of (243), and therefore, by (242),

$$\Sigma p \nabla q = -\Sigma q \nabla p. \quad . \quad . \quad . \quad . \quad . \quad (244)$$

All the work done by a vector analyst is exhibited in (244) itself, viz., the transfer of the symbol ∇ from one operand to the other, with change of sign, converts the integral of $p\nabla q$ into that of $-q\nabla p$. The previous remarks contain the justification of the process.

Now $-\nabla q$ is a polar or divergent vector, so may be any one of our divergent series, say $\mathbf{C}_2$, when q itself becomes B_2. Then

$$\Sigma p \mathbf{C}_2 = \Sigma \mathrm{B}_2 \nabla p. \quad . \quad . \quad . \quad . \quad . \quad (245)$$

Lastly, let p have the special value $1/4\pi r$; then (245) is the same as

$$\mathrm{pot}\, \mathbf{C}_2 = \mathbf{A}_2 = \Sigma \mathrm{B}_2 \nabla p, \quad . \quad . \quad . \quad . \quad (246)$$

which exhibits the divergent vector $\mathbf{A}_2$ in terms of its divergence B_2. It is the same as (240), since $\nabla p = \mathbf{r}_1 / 4\pi r^2$, if $\mathbf{r}_1$ is the unit vector from B_2 to $\mathbf{A}_2$.

§ 137. Next, substitute for q in pq a vector, say $\mathbf{g}$. The new quantity $p\mathbf{g}$ has, being a vector, both curl and divergence, in general. Considering the latter first, we have

$$\mathrm{div}\, p\mathbf{g} = p\, \mathrm{div}\, \mathbf{g} + \mathbf{g}\nabla p, \quad . \quad . \quad . \quad (247)$$

which is an example of (160). Integrating throughout any volume, we have

$$\Sigma \mathbf{N} p\mathbf{g} = \Sigma\, \mathrm{div}\, p\mathbf{g}, \quad . \quad . \quad . \quad . \quad (248)$$

as in (159), where $\mathbf{N}$ is as before. So, if the surface-integral vanishes, we obtain, by (247),

$$\Sigma p\, \mathrm{div}\, \mathbf{g} = -\Sigma \mathbf{g} \nabla p, \quad . \quad . \quad . \quad . \quad (249)$$

and, in this transformation, all the vector-analyst has to do is

Digitized by Google

to shift the operator ∇ from one operand to the other, and change the sign.

The vector $\mathbf{g}$ here has no restriction imposed upon it. It may therefore be of the general type $\mathbf{C} = \mathbf{C}_1 + \mathbf{C}_2$, giving

$$\Sigma p\mathrm{D}_2 = -\Sigma \mathbf{C}\nabla p = -\Sigma \mathbf{C}_2\nabla p \quad . \quad . \quad . \quad (250)$$

Here the portion $\Sigma \mathbf{C}_1\nabla p$ vanishes because $\mathbf{C}_1$ is circuital and ∇p is polar, which is one of the important theorems in analysis that become visibly true by following the tubes of the circuital flux in performing the summation, when the summation is seen to vanish separately for every tube. (*See* § 87).

If in (250) we give p the special value $1/4\pi r$, viz., the potential due to a unit source at distance r, we obtain

$$\text{pot } \mathrm{D}_2 = \mathrm{B}_2 = -\Sigma \mathbf{C}\nabla p = -\Sigma \mathbf{C}_2\nabla p, \quad . \quad . \quad (251)$$

showing how to pass up one step in the divergent series from a vector to the preceding scalar. It is the same as (241), remembering the value of ∇p.

§ **138.** Thirdly, we have the curl of $p\mathbf{g}$ to consider. Here, by (188),

$$\text{curl } p\mathbf{g} = p \text{ curl } \mathbf{g} - \mathrm{V}\mathbf{g}\nabla p, \quad . \quad . \quad . \quad (252)$$

Integrating throughout any region, we obtain

$$\Sigma \mathrm{V}\mathbf{N}p\mathbf{g} = \Sigma \text{ curl } p\mathbf{g}, \quad . \quad . \quad . \quad . \quad (253)$$

which is a case of (162), with $p\,\mathbf{g}$ put for $\mathbf{H}$. So, if the surface-summation vanishes, we obtain, by (252),

$$\Sigma p \text{ curl } \mathbf{g} = \Sigma \mathrm{V}\mathbf{g}\nabla p, \quad . \quad . \quad . \quad . \quad (254)$$

when the symbol $\mathrm{V}\nabla$ is moved from $\mathbf{g}$ to p, with a change of sign, as before. In this, take $p = 1/4\pi r$; then, since there is no restriction upon $\mathbf{g}$, we get, taking $\mathbf{g} = \mathbf{C}$,

$$\text{pot } \mathbf{D}_1 = \mathbf{B}_1 = \Sigma \mathrm{V}\mathbf{C}\nabla p = \Sigma \mathrm{V}\mathbf{C}_1\nabla p, \quad . \quad . \quad (255)$$

which is the companion to (251), showing how to pass up one step in the circuital series, from $\mathbf{C}_1$ to $\mathbf{B}_1$. This is equivalent to (229). The divergent part of $\mathbf{C}$ contributes nothing. That is to say, for example, the magnetic force due to a completely divergent distribution of electric current, according to Ampère's formula for the magnetic force of a current *element*, is zero. We might, indeed, argue from this, that there could not be such a kind of electric current; that is to say, that the current must be circuital, since the mathematical machinery itself, constructed on old ideas, automatically rejects the want of circuitality, and refuses to admit the purely divergent part as contributory to magnetic force. This is a perfectly valid argument, provided the test of the existence of electric current be the existence of magnetic force, which is tantamount to what Maxwell insisted upon, in another form.

For instance, if we calculate by (255) the magnetic force due to a supposititious current element at a point, simply by removing the sign of summation, we obtain the magnetic force of a rational current element, a system of circuital current resembling the induction due to a magnetised particle. (*See* § 62.)

§ **139.** Returning to the three single up-step formulæ, it will be observed that in every case we base the proof upon the vanishing of a surface-integral, viz., $\Sigma \mathbf{N}pq$, or $\Sigma \mathbf{N}p\mathbf{g}$, or $\Sigma \mathrm{V}\mathbf{N}p\mathbf{g}$. Now it is obvious that these are true if the surface be taken wholly outside the region occupied by the quantity q or $\mathbf{g}$. The value pq or $p\mathbf{g}$ is made zero all over the surface of summation. This is what occurs in the applications made. In (246) the space-summation has to include all the B_2, which represents q; it is sufficient, therefore, for the surface to completely enclose all B_2. Again, in (255), the enclosure by the surface of all $\mathbf{C}$, which represents $\mathbf{g}$, will ensure the vanishing of the surface-integral; and in (251) the same. Now, it is usual to imagine the surface to be at infinity, so that the space-summations extend over all space. This is also most convenient, in general. But caution is sometimes necessary when the quantity to be summed extends to infinity. The surface-summation then may, or may not, vanish, according to circumstances. Even if the quantity summed becomes infinitely small at infinity, the summation may still not vanish To illustrate this, it is sufficient to mention the case of a single point-source. The surface-integral of the flux it produces is finite always, being the measure of the strength of the source. At infinity the flux may be infinitely attenuated, but the surface is simultaneously infinitely magnified. But in the application of the above processes to practical cases in electromagnetism it is usually quite easy to see that the integral over the surface at infinity vanishes, owing either to the actual absence of anything to be summed, or else, when there is an infinitely attenuated quantity to be summed, of its being, per unit area, of lower dimensions than $1/r^2$. The quantity p itself attenuates to nothing, as well as q or $\mathbf{g}$, if they are existent at all at infinity.

The three up-step formulæ may, by inspection, be transformed so as to involve entirely different operations. Thus, in (241), put p for $1/4\pi r$. Then we have

$$\mathrm{B}_2 = -\text{pot } (\mathbf{C}_2/\mathbf{r}). \quad . \quad . \quad . \quad . \quad (256)$$

Do the same in (240), and we obtain

$$\mathbf{C}_2 = \text{pot } (\mathrm{D}_2/\mathbf{r}). \quad . \quad . \quad . \quad . \quad . \quad (257)$$

Finally, (229) gives

$$\mathbf{C}_1 = \text{pot } (\mathrm{V}\mathbf{D}_1/\mathbf{r}). \quad . \quad . \quad . \quad . \quad (258)$$

We may sometimes utilise these formulæ for purposes of calculation, should the integrations to be performed be amenable to practical treatment. But there is a caution to be mentioned. The quantities whose potentials are calculated by the last three formulæ are not functions of position, which are definitely distributed in space, and are independent of the position of the point where the potential is reckoned, but are definite only when this point is fixed. As you pass to another point, the potential, there is that of a different distribution from that belonging to the first point. These quantities, $\mathbf{C}_2/\mathbf{r}$, &c., are therefore not subject to the various properties of the circuital and divergent vectors already considered. For example, $\mathbf{C}_2$ is purely divergent, but $\mathrm{D}_2/\mathbf{r}$ has curl; or, $\mathbf{C}_1$ is circuital, whilst $\mathrm{V}\mathbf{D}_1/\mathbf{r}$ has divergence, and so on.

§ **140.** The transformations (244), (249), (254), or the more general ones containing the omitted surface-summations, expressed by putting the sign of summation before every term in (242), (247), (252), and converting the summation on the left to a surface-summation by the introduction of $\mathbf{N}$, as in (243), (248), and (253), are examples of what is, in the Cartesian mathematics, called integration "by parts." It is usually a very tedious and uninforming process, that is, in Cartesians, with its triple and double $\int$'s, its $d\mathrm{S}$ and $dx\,dy\,dz$, and its l, m, n. The vectorial methods go straight to the mark at once, avoid a large amount of quite useless work, and enable you to keep your attention fixed upon the actual magnitudes concerned, and their essential relations, instead of being distracted by a crowd of coordinates and components.

There are, of course, many other cases which arise of this "by parts" integration. One of the most important in connection with the circuital series of vectors, is the following:— Substitute for p in the preceding, a vector, say $\mathbf{f}$, then we shall have

$$\Sigma \mathbf{f} \text{ curl } \mathbf{g} = \Sigma \mathbf{g} \text{ curl } \mathbf{f}, \quad . \quad . \quad . \quad . \quad (259)$$

the summations being throughout all space, or, at any rate through enough of it to include all the quantities summed. The proof is that since

$$\text{div } \mathrm{V}\mathbf{g}\mathbf{f} = \mathbf{f} \text{ curl } \mathbf{g} - \mathbf{g} \text{ curl } \mathbf{f}, \quad . \quad . \quad . \quad (260)$$

which is (178) again, we have, by space-summation,

$$\Sigma \mathbf{f} \text{ curl } \mathbf{g} = \Sigma \mathbf{g} \text{ curl } \mathbf{f} + \Sigma \text{ div } \mathrm{V}\mathbf{g}\mathbf{f}, \quad . \quad . \quad (261)$$

and the third term may be at once turned into the surface-summation $\Sigma \mathbf{N}\mathrm{V}\mathbf{g}\mathbf{f}$. If this vanish, as usual, then (259) follows.

Applying this result to the series of circuital vectors $\mathbf{A}_1$, $\mathbf{A}_2$, $\mathbf{A}_3$, &c., each of which is the curl of the preceding, we obtain various equivalences. Thus,

$$\Sigma \mathbf{D}_1^2 = \Sigma \mathbf{C}_1\mathbf{E}_1 = \Sigma \mathbf{B}_1\mathbf{F}_1 = \Sigma \mathbf{A}_1\mathbf{G}_1, \quad . \quad . \quad (262)$$

through all space. Operate on one member by curl and on the other by $(\text{curl})^{-1}$, to pass from one form to the next. Also

$$\Sigma \mathbf{D}_1\mathbf{E}_1 = \Sigma \mathbf{C}_1\mathbf{F}_1 = \Sigma \mathbf{B}_1\mathbf{G}_1 = \Sigma \mathbf{A}_1\mathbf{H}_1, \quad . \quad (263)$$

in a similar manner; and so on.

Digitized by Google

In any of these summations we may convert either of the circuital vectors involved to a general vector by adding any divergent vector. For we see, by (259) that if $\mathbf{f}$ is polar, the right summation vanishes, and therefore so does the left. So $\Sigma \mathbf{D}_1^2$ is the same as $\Sigma \mathbf{D}_1\mathbf{D}$, or $\Sigma \mathbf{D}_1\mathbf{D}_2 = 0$. Similarly, $\Sigma \mathbf{C}_1\mathbf{F}_1$ is the same as $\Sigma \mathbf{C}\mathbf{F}_1$, or the same as $\Sigma \mathbf{C}_1\mathbf{F}$, since $\Sigma \mathbf{C}_1\mathbf{F}_2 = 0$, and $\Sigma \mathbf{C}_2\mathbf{F}_1 = 0$. It will be understood here that the suffix 1 refers to the circuital vectors entirely, and the suffix 2 to the divergent vectors, and that $\mathbf{C} = \mathbf{C}_1 + \mathbf{C}_2$, &c.

But we cannot generalise *both* vectors at the same time. Take $\mathbf{CF}$ for example. We have,

$$\Sigma \mathbf{CF} = \Sigma (\mathbf{C}_1 + \mathbf{C}_2)(\mathbf{F}_1 + \mathbf{F}_2) = \Sigma \mathbf{C}_1\mathbf{F}_1 + \Sigma \mathbf{C}_2\mathbf{F}_2, \quad (264)$$

so that the summation of the scalar product of the two divergent vectors now enters. The series of divergent vectors and their intermediate scalars have properties similar to (262), (263).

(To be continued.)

SAFETY FUSES.

BY CLARENCE P. FELDMANN.

The problem which I have tried to solve experimentally is simply the following. If for any set of terminals the fusing current for a fuse wire of given material, given diameter and given length be known, what empirical formula must be employed to calculate the fusing current for any other length of the same wire, clamped between the same set of terminals?

In his excellent Paper, "On the Relation which ought to Subsist between the Strength of an Electric Current and the Diameter of Conductors to Prevent Overheating," Prof. George Forbes* mentioned some experiments which he had made in 1881 to determine the fusing current of lead wires. The results he obtained are tabulated below. Finding that the fusing current for a wire of given diameter, d, increased very rapidly with decreasing length, l, Prof. Forbes pointed out that to avoid the cooling influence of the terminals, the length should be taken equal to three hundred times the diameter—

$$l = 300\, d.$$

At about the same time Mr. W. H. Preece† determined experimentally the current that raised the temperature of small conductors in air to the fusing point. In this, the first of his Papers, Mr. Preece had already pointed out‡ "how the cooling effects of the terminals or binding screws might vitiate the results, and how necessary it was to experiment on wires of sufficient length to prevent any error occurring from this cause." He used lengths of 6in. to determine the constants for wires free from the cooling effect, but lengths of 1¼in. with massive terminals to determine the constants for wires used in practice as cut-outs. Mr. Preece's last constant, a, for lead §, giving the current C required to fuse a wire of diameter d by the expression—

$$C = 1379\, d^{\frac{3}{2}},\ d \text{ being expressed in inches,}$$

$$\text{or } C = 10{\cdot}77\, d^{\frac{3}{2}},\ d \text{ being expressed in millimetres,}$$

has been widely used on the Continent under the latter form, without any statement that it was only strictly true for a certain minimum length.

In 1883 Reinisch ‖ fused lead wires of 2 mm. diameter of various lengths; but as he only intended to prove Joule's law by his experiments, the attention paid to his work was small. The first who approached a solution of the problem was a member of the Technical Society of the Russian Empire, whose name—Skrschinski—however, cannot easily be pronounced by an English tongue.

Skrschinski's Paper was read on December 17, 1890, and is published in the third number of the Russian journal, *Electritschestwo*, and Prof. Nicolai von Ozmidoff, of Riga, had the kindness to communicate me its contents. The Paper contains a great many valuable remarks and results of tests, only some of which, however, were confirmed by my own experiments. As to the diameter, Skrschinski proposes to take no lead wire under 0·5 mm. or over 2 mms., as the former is too easily torn to pieces, and the latter is apt to heat the terminals more than necessary, and to cause irregular action of the fuse, owing to the fact that in lapse of time wires of this and larger diameters will become made up of two co-axial parts; the interior of lead, the exterior of oxidised lead, which hinders the fusion, or with a too strong current, fuses with an explosion, scattering about the over-heated interior parts, which are fused long before the exterior ones.

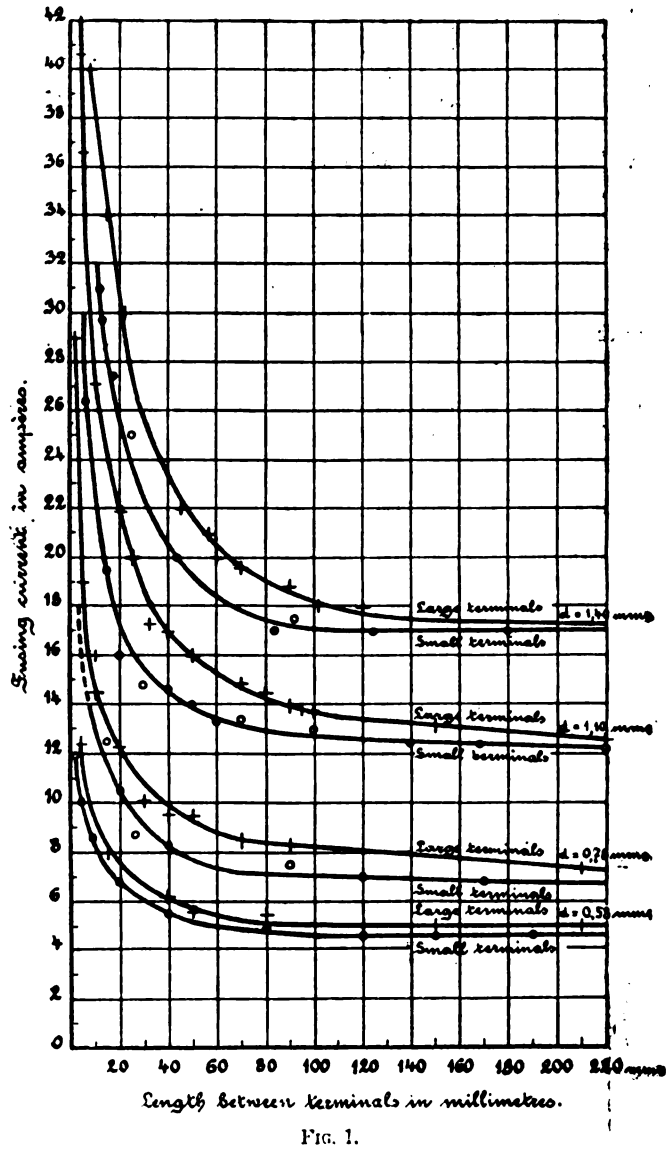

FIG. 1.

The wire always fuses midway between the terminals, and if the lengths are small, the cooling effect of the terminals suffices to let the lead wire become red hot, or even orange, corresponding to a temperature of nearly 1,000°C. Personally, I have never observed the orange-colour, though I used lengths from 400 mms. down to 2 mms., and I never happened to get red-hot wires with lengths over 1in., as Skrschinski did, though for lengths at or about ½in. and less the wire became gradually of a dark bluish grey, then of a dirty brown colour, till at last it was sending out light, like an incandescent lamp burning with a too low voltage.

In his experiments, Skrschinski determined the minimum current that would fuse a lead wire of given length and diameter, passing the current of a battery of accumulators through a liquid resistance, an ammeter and the fuse to be tested. My arrangement was nearly the same, only the resistance I used was of different construction, being built up of

metal spirals that could be joined in parallel. Skrschinski found that for each of the wires he tested, the product of the length l into the square of the current C, $C^2 l$, was constant, being for—

$d = 0{\cdot}62$ mms.	$C^2 l = 2{,}325 = (9{\cdot}938)^4 \times d^3$	(for values of l > 9 mms. < 47 „)
0·82 „	$5{,}448 = (9{\cdot}97)^4 \times d^3$	„ „ — — „
1·10 „	$13{,}233 = (9{\cdot}986)^4 \times d^3$	„ „ > 20 „ < 60 „
1·55 „	$36{,}634 = (9{\cdot}96)^4 \times d^3$	„ „ > 18 „ < 71 „

so that he combines all his results in the approximate formula

$$C^2 l = 10^4 d^3.$$

This formula is remarkably simple, but I am sorry to say that it does not agree with the results I obtained, which are tabulated in Table I., and plotted out in the accompanying Fig. 1.

Table II. — *Minimum Currents necessary to Fuse Alloy Strips 0·5 millimetre thick, b millimetres wide, and l millimetres long.*

	$b=5$		$b=7$		$b=10$

60	10·4	10·5	13·8	14·3	20·7	20·6
80	10·0	9·8	13·2	13·3	19·9	18·9
100	9·8	9·2	12·9	12·6	19·3	18·1
120	9·8	8·8	12·7	12·0	18·9	17·3
140	9·8	—	12·5	—	18·6	—
160	9·8	—	12·4	—	18·2	—
180	9·7	—	12·4	—	17·9	—
200	9·7	—	12·2	—	17·5	—

All the tests were made with two pairs of terminals, whose dimensions in millimetres and weights may be taken from Figs. 2 and 3. These terminals had not been made for the special purpose; they were taken from some apparatus, and this fact may account for the various borings which the drawings show. The material of the fuse wires was not pure lead, but some alloy of lead and bismuth. The approximation between the observed values of the fusing current and those calculated from the empirical formula,

$$C^2 \sqrt{l} = a \cdot d^3,$$

is as close as may be expected from the nature of the experiments, which, in themselves, show the remarkable fact that even if Skrschniski's formula be right for the terminals he used it will by no means hold good for anybody else's terminals.

From my own formula and for the terminals I used I found, with the large terminals (Fig. 2):—

$d = 0{\cdot}58$ mms.	.....	$C^2\sqrt{l} =$ 258	.....	$a = 1{,}320$
0·78 „	.....	650	.....	1,370
1·10 „	.....	1,850	.....	1,390
1·10 „	.....	1,850	.....	1,390
1·40 „	.....	3,500	.....	1,270
Mean value of a				1,350

with the small terminals (Fig. 3):—

$d = 0{\cdot}58$ mms.	.....	$C^2\sqrt{l} =$ 205	.....	$a = 1{,}050$
0·78 „	.....	460	.....	970
1·10 „	.....	1,350	.....	1,030
1·10 „	.....	1,350	.....	1,030
1·40 „	.....	2,700	.....	980
Mean value of a				1,000

or $C^2\sqrt{l} = 1{,}350\, d^3$ for the large terminals (Fig. 2),
and $C^2\sqrt{l} = 1{,}000\, d^3$ for the large terminals (Fig. 3).

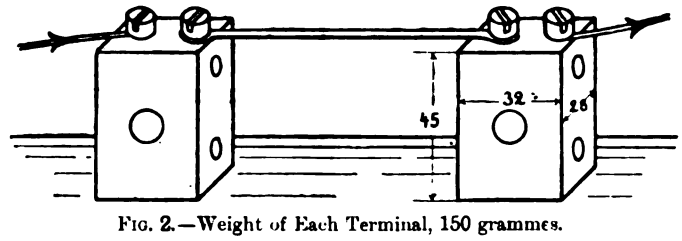

Fig. 2.—Weight of Each Terminal, 150 grammes.

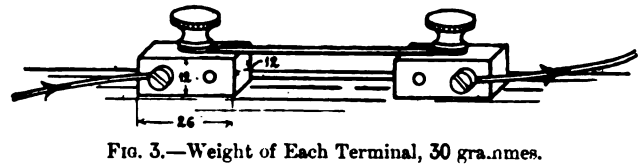

Fig. 3.—Weight of Each Terminal, 30 grammes.

Taking $l = 6$ inches, and measuring d in inches we have

$C = 1{,}340\, d^{\frac{3}{2}}$ for the large terminals and the alloy wires,

$C = 1{,}155\, d^{\frac{3}{2}}$ for the small terminals and the alloy wires, whilst Mr. Preece gave

$C = 1{,}357\, d^{\frac{3}{2}}$ for his terminals of medium size and lead wires;

If I may quote the authority of Prof. George Forbes, I should like to point out that some of his results of 1881 are practically in consonance with the empirical law $C^2\sqrt{l} = a \cdot d^3$. Prof.

Digitized by Google

Forbes gave for a lead wire of 1·28 mms. diameter the following series of observations :—

$l = 300$ mms.	.....	$C = 9{\cdot}05$	$C^2\sqrt{l} = 1{,}555$
150 „	.....	12·37	1,870
75 „	.....	12·75	1,410
50 „	.....	13 5	1,290
25 „	.....	16·87	1,425
Mean value of $c^2\sqrt{l}$ =	.....		1,500

from which, however, a would only be about 715. As the results were three years old when Prof. Forbes published them,

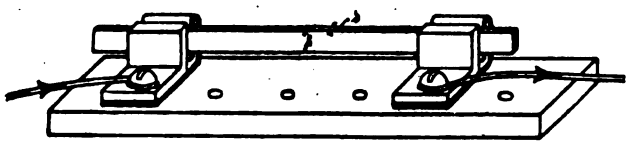

Fig. 4.—Weight of Each Terminal, 30 grammes.

it is possible that there may be some slip in the diameters. This view seems to be supported by the fact that in the rest of the table

$d = 0{\cdot}55$ mms.	...	$l = 25$ mms.	...	$C = 0{\cdot}78$	amperes.
0·78 „	...	25 „	...	0·937	„
0·94 „	...	25 „	...	1·125	„
1·03 „	...	25 „	...	8·2	„
1·03 „	...	225 „	...	6·0	„

either the small diameters or their corresponding fusing currents are obviously wrong.

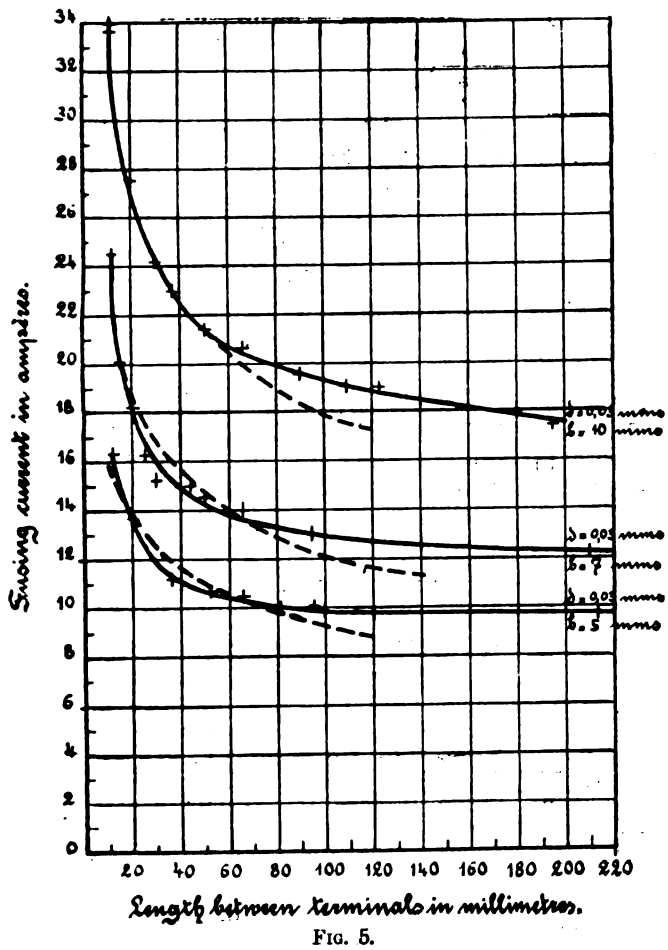

Fig. 5.

I have also experimented upon fuses in the form of strips shown in Fig. 4. The empirical law $c^2\sqrt{l} = a\,S$, if we denote by S the surface of the strip, holds good in this case too, but its range is narrower than with round wires. The tests were made with strips $\delta = 0{\cdot}05$ mms. thick, and b various widths, $b = 5$, 7 and 10 millimetres; two of these strips were fastened with shellac varnish upon the sides of a thin strip of cardboard of corresponding width. The results are given in Table II., and are plotted out in Fig. 5, where the dotted lines show the calculated, the full lines the observed fusing currents. The currents were calculated from the values

$C^2\sqrt{l} =$	849 for	$\delta = 0{\cdot}05 \times 2$ mms., and	$b =$	5 mms.	wherefrom	$a = 332$
$C^2\sqrt{l} = 1{,}580$	„	$= 0{\cdot}05 \times 2$ „	„	$= 7$ „	„	$= 318$
$C^2\sqrt{l} = 3{,}271$	„	$= 0{\cdot}05 \times 2$ „	„	$= 10$ „	„	$= 327$
Mean value of a						$= 326$

The approximation obtained by the empirical formula,

$$\therefore\ C^2\sqrt{l} = 326 \times b\,2\,\delta\,(b + 2\,\delta),$$

is, however, less than in the case of round wires.

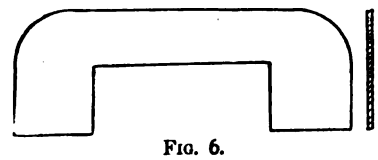

Fig. 6.

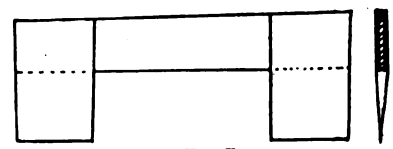

Fig. 7.

The influence of a small change in the terminals was shown by a simple experiment. Two sets of fuses of exactly the same dimensions l, b, and δ were tried, of which one had been provided with a small wrapping of brass sheet round the ends. (Figs. 6 and 7).

Dimensions of strip.	Bare strip.		Strip with enlarged ends.		Terminals.
$\delta = 0{\cdot}05$ $b = 8$ $l = 24$	J = 20	$a = 302$	J = 23	$a = 400$	Smaller than Fig. 7.
$\delta = 0{\cdot}075$ $b = 10$ $l = 37$	J = 29	$a = 334$	J = 34	$a = 460$	like Fig. 4.

The weight of each of the terminals smaller than those represented in Fig. 4, was 10 grammes, the weight of each of the other terminals was 30 grammes.

By my experiments I only think I have proved that it is absolutely necessary to test fuse wires exactly under the conditions of their normal use, within the clamps that are to hold them, these clamps being fixed upon the proper base, and the whole fuse being covered with a metal or porcelain cover, as in practical use. There is no doubt that, with open fuses, convection plays a prominent part in the "going" of a fuse, and that a fuse in cold open air will take a higher current than a fuse of similar size near the ceiling of a hot engine-room.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, May 27th.

LONDON CHAMBER OF COMMERCE.

2.30 p.m. Annual Meeting of the Electrical Trades Section at Botolph House, Eastcheap.—The agenda will be found in our "Notes" column.

PHYSICAL SOCIETY.

5 p.m. Ordinary Meeting. Paper to be read: "On the Present State of our Knowledge of the Connection between Ether and Matter.—An Historical Summary." By Prof. O. J. Lodge, F.R.S.

OLD STUDENT'S ASSOCIATION.

7.30 p.m. Smoking Concert at Masons' Hall Tavern.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Emotional Expression." By Sir James Crichton-Brown, F.R.S.

TUESDAY, May 31st.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Annual General Meeting to receive the Report of the Council, and to elect the Council and Officers for the ensuing year.

SOCIETY OF ARTS.

8 p.m. Applied Art Section. Paper to be read: "Lustre Ware." By William de Morgan.

FRIDAY, June 3rd.

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.
[VOLUME II. nearly ready.]

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Vol. I. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.
Several Further Volumes in Active Preparation.

NOW READY, IN TWO VOLUMES. PROSPECTUSES FREE.
"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*
Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

TRAIN-LIGHTING.

Of the three systems of train-lighting—direct driving from a small engine; discharge from accumulators without engine or dynamo; and dynamo driving from an axle—the last seems to be the most promising. Accumulators are necessary to supply the lights not only while the train is at rest, but when it is running at a speed too slow to drive the dynamo at a useful voltage. The charging of the batteries is effected only while the train is running above this speed, and, of course, only during the daytime. The ratio of the period during which charging is possible to the period during which the batteries are called upon to supply the current determines the minimum speed. This varies widely on different lines, and with different trains and classes of trains. Neither engineers nor traffic managers are able to give accurate information on that point, and several failures have been due to neglect of this consideration. Increase of speed above the minimum does not contribute any useful effect, but has to be neutralized by the action of a governor introducing resistance in the fields, or rocking the brushes; or by some other means for preventing a rise of the voltage, such as a second dynamo, or compound winding with back turns. Such a governing apparatus has only a limited range, and varies from one to three or one to four. The HOLMES' double dynamos on the Midland Railway cut in when 25 miles an hour is attained, and maintain a constant pressure of 50 volts up to 75 miles an hour. The full pressure is thus attained at one-third of the maximum speed. The governing arrangement of Mr. HOUGHTON, of the London, Brighton, and South Coast Railway Company, adapted to a Brush dynamo, enables the dynamo to begin to generate at one quarter of the full speed. If this were equivalent to the effective working of the dynamo during two-thirds or three-quarters of the whole of the journey there would be little or no difficulty. It is not a question of mere speed, for the gear could be adapted for either fast or slow trains; but the difficulties arise with trains stopping at many stations, when it will be found in a large number of cases that the period during which charging is possible is

Digitized by Google

less than that during which the batteries are called on to provide current, unless a very wide range of working of the dynamo is arranged for. With a wide range the dynamo must be larger, for it must be able to do the whole work at a slower speed. Another difficulty arises when trains have to be broken up; the batteries are then subjected to unequal charge and discharge, and unless there is very ample provision for charging they are sure to deteriorate.

A year ago there were sixteen electrically lighted trains on the Brighton line, and six more were being fitted; on the Great Northern there were six, and two were being fitted; and on the Midland there were eight main-line and two local trains, making, according to Mr. LANGDON'S Paper on the subject, a total of 365 coaches and 57 vans electrically lighted. The Brush Electrical Engineering Company have supplied some 60 dynamos for train lighting which may be said to have advanced well beyond the experimental stage. Notwithstanding the success and increase of this branch of electric lighting, it must be remembered that it presents most unusual difficulties, and should not be attempted, as has often been done, without most careful consideration of the conditions of each particular service. The early attempts in this direction were sometimes entrusted, after they had left the hands of the contractors, to the supervision of telegraph superintendents, who, unlike Mr. HOUGHTON and a few others, knew nothing of dynamos or accumulators.

The various advantages which electric light presents in domestic illumination are not felt in train lighting, since the products of combustion of either gas or oil lamps are got rid of; and no accident has yet resulted from the use of compressed gas. The lighting of the London and North-Western trains running from the Mansion House to Broad-street is hard to beat; but the gas is very costly, and an expensive generating and charging plant has to be provided. It is remarkable that the value of electric lighting in connection with the two great systems of steam locomotion should differ so widely. It is simply indispensable on passenger steamers, where it is the greatest boon, and if the cost were double it would make little or no difference; and it is, moreover, easy to arrange and fit, there being no need for batteries or regulation. In passenger trains, on the other hand, the difficulties are peculiar, the mechanical and electrical details are very complicated, the light presents no advantages to the passengers, and the whole thing is simply a question of relative cost.

OBITUARY.

PETER WILLIAM WILLANS.

It is with deep regret that we have to announce the death of Mr. P. W. Willans, founder and head of the firm of Willans and Robinson, of Thames Ditton. Mr. Willans was driving from his residence at Frimley on Monday afternoon to his works, when the horse bolted and threw him on to a heap of stones, causing instant death from concussion of the brain. Mr. Willans was 41 years of age.

At 16 he entered upon a five years' apprenticeship in the shops and drawing office of Messrs. Carrett and Marshall (now Hathorn, Davey and Co.), engineers, Leeds, and spent two years chiefly in the drawing office of Messrs. John Penn and Sons, of Greenwich. Whilst with this firm he invented the first form of his three-cylinder high-speed engine, which was patented in 1874, the earlier examples being made by Messrs. Tangyes and Messrs. Hunter and English. From 1875 to 1880 he superintended the manufacture of his engines at the works of the latter firm at Bow. Mr. Willans soon saw that in order to develop the high-speed direct-acting engine to its fullest extent, it was necessary to start works of his own; and in 1880, in partnership with Mr. Robinson, the works at Thames Ditton were commenced from small beginnings, the business being at first confined to launch and yacht engines. The application of the Willans engine to the direct driving of dynamos caused the rapid development of the works; and though the business received a check when a fire destroyed the erecting shops, the reconstruction of the premises gave Mr. Willans an opportunity for putting down a most perfect example of an engine-manufacturing plant. The conditions demanded for the driving of dynamos have done much to improve the design and construction of steam-engines in this country; but many a valuable lesson has been learned by dynamo builders in the works at Thames Ditton, and many important developments have originated from the opportunities afforded by the careful testing which has been carried out there.

Although Mr. Willans' name is best known in connection with the manufacture of a particular form of engine, his early death is to be deplored on account of his knowledge of the application of thermo dynamics to the economical use of steam. His Paper on "Non-condensing Steam Engine Trials," read before the Institution of Civil Engineers on March 19, 1888, dealt with only a few of the important points of which he had so thorough a grasp; and we understand that he has left another Paper on the subject. Though he could find little time to write elaborate Papers, the part which he took in discussions at the Institution of Civil Engineers and elsewhere revealed how much he might have communicated. His remarks after Mr. Imray's Paper on "High Speed Motors" on November 24, 1885, Mr. Allen's Paper on "Auxiliary Engines" on January 13, 1891, and after Mr. Crompton's Paper on "The Cost of the Generation and Distribution of Electrical Energy" on April 7, 1891, were of the greatest value. Though not unfrequently finding himself opposed to rival manufacturers, he never was heard to make an unkindly remark or criticism of the work of others. In discussing Mr. Allen's paper on "Auxiliary Engines," he referred to a fan engine at the Woodthorpe Colliery, which had been at work for five years. It had run as much as nine months without being stopped, and it was locked up by itself at night. His partner being down there on one occasion, asked to be allowed to see the engine. He was told that the man had gone home and had taken away the key.

The high economy attained by his engines when used for electric lighting plant is so well known and so universally acknowledged, that it is unnecessary here to enlarge upon it; but it is perhaps not so generally known that the main cause of these great successes was the care and forethought with which Mr. Willans himself adapted his machinery to suit the special requirements and special needs of the rapidly developing industry. The great mechanical success of the Willans engine has done much to establish confidence in high-speed driving among engineers; but this alone would not have established the reputation which the inventor has built up. Proud as he was of the silent running and excellent wearing qualities of his engines, due to careful design and the best workmanship, the real aim of his work, as far as may be judged at present, was economy of steam; and in this is included not only the use of direct-driving and doing away with belts and counter-shafting, but the management of boilers, the proper use of condensing, and the selection of the size of unit of plant for particular conditions. He lived, fortunately, to see the successful application of his work to mill-driving; and at a recent meeting of the Society of Arts, described during a discussion how the starting of an engine of about 659 H.P. in a cotton-mill at Bolton was really child's play to what an electric light engineer had to do, it was so simple, in comparison; showing, perhaps, what a high view he took of the proper carrying out of the driving of dynamos.

In private life Mr. Willans' character was a very perfect one. His kindliness of nature and thoughtfulness for others will cause him to be long and regretfully remembered by his large circle of friends; but the loss which electrical engineering has sustained by his death will be only estimated at its full value when those who have so long worked with him and profited by his advice begin to feel that they no longer have him with them to aid them.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 6.*)

[**Erratum.**—In the reference to Mr. Webb on page 5, *The Electrician*, May 6, in connection with the underrunning of cables, an error was inadvertently made in the initials to the name, which we hasten to correct by saying that the name should read Mr. F. C. Webb.]

10. Capacity of Tanks.—To obtain some idea of the general carrying capacity of a repairing steamer, take for instance a vessel such as the "Electra," belonging to the Eastern Telegraph Company, the tanks in which are of the dimensions given above. Consider first the largest tank (No. 2), the position of which with regard to the section of the ship is indicated in Fig. 30. The upper edge of the tank is just below the main

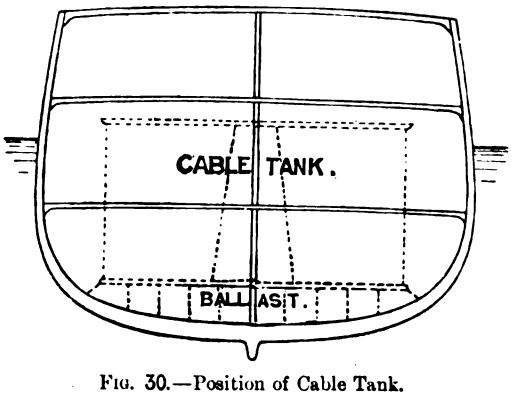

FIG. 30.—Position of Cable Tank.

deck, and the bottom rests upon the water ballast tanks, the height being 12ft. The cone is 6ft. diameter below and 3ft. above, so that considering the tank two thirds full of cable the diameter of the cone at the topmost flake would be 4ft., and the mean inside diameter between this flake and the lowest one would be 5ft. (Fig. 31). The tank being two-thirds full will be filled to a height of 8ft., and it will be necessary first to calculate the cubic capacity of the tank up to this level, exclusive of that of the cone. The capacity of the cone to the level of 8ft. is

$$(5)^2 \times 0{\cdot}7854 \times 8 = 157 \text{ cubic feet,}$$

and the tank being 25ft. diameter its capacity up to same height is

$$(25)^2 \times 0{\cdot}7854 \times 8 = 3{,}927 \text{ cubic feet.}$$

Deducting the capacity of cone, we have 3,770 cubic feet available coiling space.

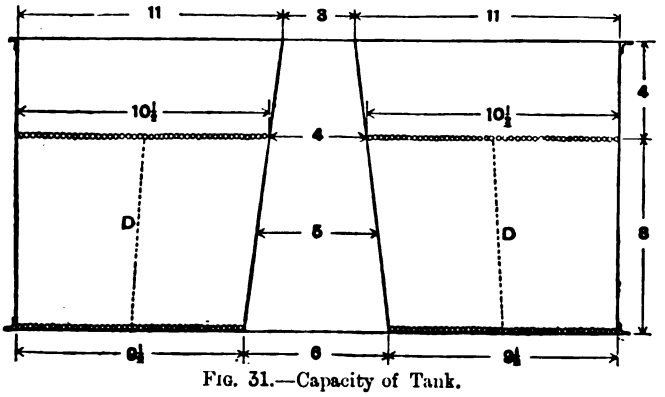

FIG. 31.—Capacity of Tank.

Now suppose that the cable coiled in is the deep sea type, this being the kind of which the largest quantity is required. The overall diameter is as closely as possible ¾in. ($\frac{1}{16}$ foot), and, therefore, the cubic contents or capacity of one knot of this type is equal to

$$(\tfrac{1}{16})^2 \times 0{\cdot}7854 \times 6{,}087 = 18{\cdot}67 \text{ cubic feet.}$$

We have now to consider the space this cable occupies when coiled in tank. It is quite clear that between each turn of cable there are spaces left unutilised, on account of the circular cross section of the cable. The proportion of this waste space varies according to the size of cable, and it is found that an allowance has to be made of from 10 per cent. in small cables to about 25 per cent. in large types for this unoccupied space. After the cable has been stowed in tank for some time it settles down, and the waste space is diminished, the decrease amounting sometimes to 5 per cent.

There is also some extra space taken up by the feather-edge in coiling (Fig. 32). The cable is coiled from the outside of the tank inwards, and when the innermost turn of one flake is laid next the cone the cable is taken straight across over this flake to the outside to commence coiling the next flake. The part so taken across and lying between each flake is called the "lay-out," and in the figure is shown in section by the small circle. The feather-edge is made with strips of deal wood about five or six feet long, and cut with a wedge-shape section, as shown, so as to pack up the lay-out and form a gradual rise and fall for the turns of the upper flake as they cross it. For the deep sea type which we are now considering, a fair allowance to make for waste space in coiling is 15 per cent.—that is, one knot of this cable, which contains 18·67 cubic feet, as calculated from its own dimensions, would, when coiled, take up 15 per cent. more space, or 21·47 cubic feet. The length of cable in this tank when two-thirds full is now easily calculated. The available space being 3,770 cubic feet, and the space taken up per knot being 21·47 cubic feet, the length coiled in is

$$\frac{3770}{21{\cdot}47} = 175 \text{ knots.}$$

In a similar manner the forward tank (No. 1), which is 14ft. diameter and 8ft. deep, when two-thirds full would hold 33 knots of the same type, and the two tanks aft, both about 17ft. diameter and 7ft. deep, would each contain 45 knots. Thus, with all four tanks only two-thirds full, a vessel of this size (1,096 tons) could carry 298 knots of deep sea cable. The cubical capacity, exclusive of cone, is usually worked out for different heights in the tank, separated by very short intervals, so that at a moment's notice the approximate length of any given type coiled in can be ascertained.

FIG. 32.—Feather edge in coiling.

In picking up during repairs the lengths coiled in tank generally only occupy a few flakes, and it is often desirable to know the length of cable per flake for different types, as coiled in each of the tanks. This may be observed, as the cable is being coiled, by the indications of the rotometer, but is also very readily calculated. Taking, for example, the above tank (Fig. 31), there will be 168 turns of cable to the topmost flake, since the width across from cone to outside of tank is 10ft. 6in. (or 126in.), and the cable is ¾in. diameter: hence

$$\frac{126 \times 4}{3} = 168 \text{ turns.}$$

Further, the mean length per turn is found by multiplying the mean diameter of the flake by 3·1416, and the mean diameter is found by taking half the sum of the diameters of cone and tank at that height. Thus, the flake, at the height of 8ft. in the tank, has a mean diameter of

$$\frac{4+25}{2} = 14{\cdot}5\text{ft,}$$

and this, multiplied by 3·1416, gives 45·55ft. as the mean length of cable per turn. Hence, the length of cable per flake is

$$168 \times 45{\cdot}55 = 7{,}652\text{ft. or } 1{\cdot}257 \text{ knot.}$$

The mean diameter increases slightly down to the lowest flake, as shown by the lines DD, on account of the cone; hence, the mean length per turn increases: but, at the same time, the number of turns per flake decreases more rapidly, and the length of cable per flake is consequently less, the lowest flake, by a similar calculation, containing 1·216 knot. The above figures represent very closely the cable-carrying capacity of repairing steamers of the average tonnage; but, before leaving

* All rights reserved.

Digitized by Google

the subject, it may be of interest to consider the capacity of one of the largest cable steamers afloat. These steamers, which are from 3,000 to 5,000 tons, are of sufficient capacity to take out whole cables of one to two thousand miles long in one shipment, with all the necessary gear and accessories required in such large undertakings. Besides this, they are able to carry a coal supply sufficient for four or five months' continuous work. The cable ship "Scotia," of 4,667 tons, some time ago performed four months' cable work in the Atlantic, returning afterwards with 1,100 tons of her original stock of coal. The cable ship "Silvertown," of 4,935 tons, when on the Central and South American expedition, carried 4,881 tons of cable, 1,660 tons of coal, 111 tons of buoys, chains, cable-gear, and office and telegraph fittings, and 159 tons of provisions and water, making a total of 6,811 tons. The above weight of cable represented a length of 2,370 knots, the same vessel having carried as much as 2,600 knots on one trip. Of vessels of this description our nation may be justly proud. Their magnificent and powerful build, their enormous cable and fuel capacity, their heavy equipment of grapnels, chains, buoys, brakes, and steam-gear for ocean work under the heaviest strains; their light equipment of electrical apparatus, in the design of which the highest scientific skill has been brought to bear—all tend to mark such vessels as grand floating monuments to the enterprise, the pluck, the dogged perseverance, the scientific ability, and the high engineering and nautical skill of the greatest maritime nation in the world.

One of these fine cable ships, the "Silvertown," belonging to the India Rubber, Gutta Percha, and Telegraph Works Company, is illustrated herewith from a photograph (Fig 33). She is 350ft. long, 55ft. broad, and 34ft. 6in. deep, is fitted with engines of 1,800 I.H.P., and steams at a speed of 10½ knots, with a consumption of 30 tons of coal per day. She carries three tanks of large proportions, each one being 32ft. in depth, and the largest (the main tank) being 53ft. in diameter. This tank has consequently over 70,000 cubic feet capacity, or about 67,000 cubic feet exclusive of the cone. When filled with cable up to the height of 29ft. the coiling space, exclusive of the cone, is 61,221 cubic feet, the space taken up by the cone at this height being 2,758 cubic feet.

Now, we found above that one knot of deep sea cable occupied 21·47 cubic feet of coiling space, and, therefore, the "Silvertown's" main tank will hold

$$\frac{61221}{21{\cdot}47} = 2{,}850 \text{ knots}$$

when filled to the height of 29ft.

The fore tank on this vessel in 46ft. in diameter and the aft tank 51ft. It is not usual to load up the tanks more than to a depth of 23ft., or about two-thirds full, except for cables of a light and bulky type.

For readily computing the lengths of cable stowed in tank, the capacities of the tank and cone at various heights are kept for reference, and marked on a large elevational drawing of the tank. It is then only a matter of observation, while coiling, of the height to which the tank is filled, and knowing the capacity of each type of cable and the space it occupies when coiled, the length stowed in tank is at once obtained by simple division. The light intermediate type has a capacity of about 40 cubic feet per knot, and occupies about 46 when coiled; the heavy intermediate has about 58 cubic feet per knot and 78 as coiled; and the shore end type has about 185 cubic feet per knot and 230 when coiled.

When carrying 6,390 tons the mean draught of the "Silvertown" is 28ft, and with the load of 6,811 tons alluded to above, her draught was 27ft. forward and 29ft. 6in. aft, the greatest draught of any merchant steamer except the "Great Eastern." The coal bunkers on board have a combined capacity of 1,300 tons, besides which over 1,000 tons can be stowed in the fore hold. With such a stock of fuel this vessel can steam greater distances and remain continuously at work without coaling for longer periods than any other existing cable ship. The "Silvertown" is now at sea laying the new cable between St. Louis, Senegal, and Pernambuco, for which expedition she left the Thames a few days ago with 2,160 knots of mixed cable, including shore ends, and representing a dead weight of 5,000 tons.

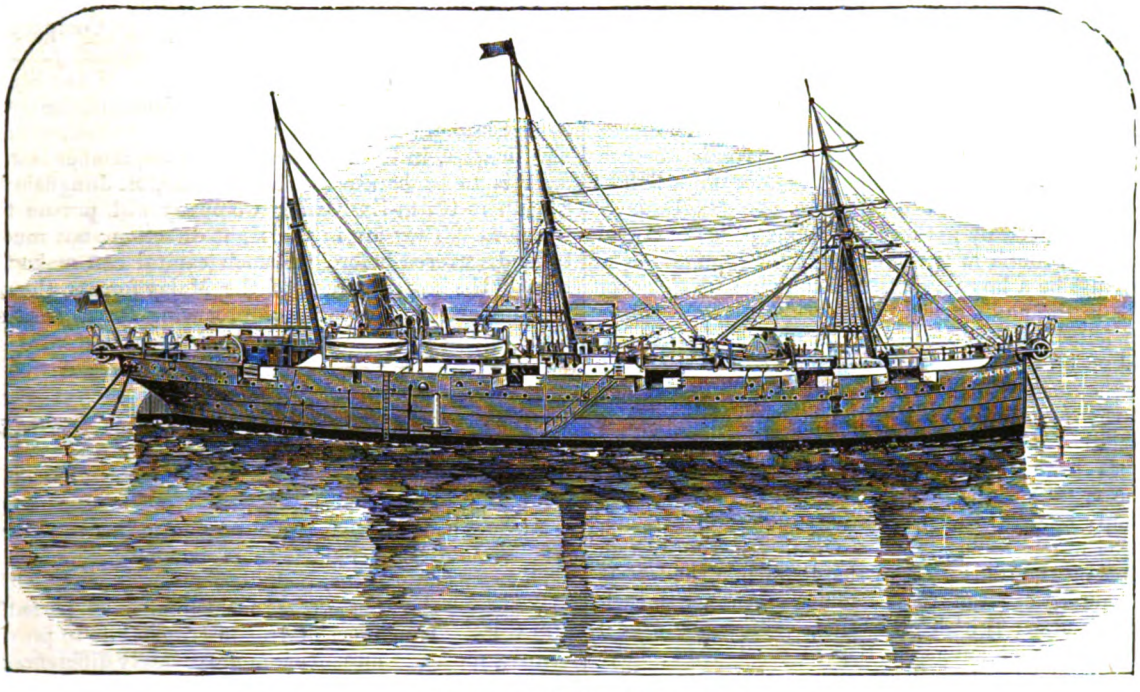

FIG. 33.—Cable Ship "Silvertown.

(To be continued.)

THE CULTIVATION AND COLLECTION OF GUTTA-PERCHA.

Under the above heading we gave in our issue of May 20th an epitome of a report made by M. Eugène Sérullas to the Société d'Encouragement on his latest expedition to Malaysia to investigate the gutta-percha supply.

The question of the supply of gutta-percha is a large and important one, of the deepest interest to all who are connected with the *use* of electricity; and any contribution to our knowledge of its supply, or the sources of its supply, which is authentic and reliable, will be cordially welcomed. If M.

Digitized by Google

Sérullas has discovered means for "the regeneration of exhausted sources" it goes without saying that his name and fame are assured. To the present writer, a few months ago, one of the highest authorities at Kew Gardens said, "We know extremely little about the trees which produce the gutta-percha of commerce;" and this statement was fully demonstrated when he exhibited the specimens of *isonandra* preserved in the Museum, which were a few dried leaves bearing legends dating from 1834 to 1858.

Authorities do not agree as to the origin of the name *gœta*, *guettah*, *getah*, or *gutta*; nor are they agreed to whom the honour is due of being the first European to bring to Western notice the elastic vegetable gum used by the Malays for weapons of war or vessels of domestic use. But all authorities agree that the present method of procuring this gum is wasteful in the highest degree, and has naturally resulted in denuding the forests in all easily accessible places of the Malay Peninsula of their richest jungle tree.

Gutta-percha has been known to European commerce for 60 years; and for 35 to 40 years there has been a large and increasing demand, which to-day is satisfied, as it was 40 years ago, by the Chinese middlemen employing the Malay natives to range the jungle, and either (1) cut the trees down if they are sufficiently large, "ring" them, and gather by rapid process the exuding sap from the trunks and large branches. (2) If the trees are too small to yield a sufficiently large harvest to repay the time in felling, to pierce them in a few places and collect by slow process the exuding sap. In the former case the tree is felled close to the ground; at about every 12 inches on the trunk and larger limbs a V-shaped groove is notched through the bark right round the trunk; the juice immediately appears and coagulates into a dull white viscid substance, which the natives collect by gathering a little pellet of it and rolling it round and round in the groove till the gum ceases to flow. There must be a large quantity of the gum which never leaves the cells in the undisturbed bark. In the latter process the tree is not felled. Holes are bored by an augur irregularly over the trunk, a bit of palm leaf or part of a cocoanut shell is fixed to catch the gum. These borings must eventually damage the tree, and the quantity gathered from these small trees is exceedingly small. Naturally all the forests in civilised and settled Malaysia have been exploited. In the three colonies that form the Straits Settlements, Singapore, Penang, and Malacca, the only *isonandra* to be found are under 30 years old, too young to be worth felling for the yield. In the British protected States on the south-west of the Peninsula the forests are similarly denuded of large trees. Pahang, on the north-east, has, since it came under British protection, offered a new field for "gutta getters," and gangs of Borneo coast tribes have turned their attention to these Pahang jungles during the past two years, and have pursued their wasteful method with fairly good results. Borneo has all along produced the greatest quantity of Straits gutta, and its enormous extent of jungle country still promises for some years to keep up the supply. But naturally this must be gathered farther and farther from the coast.

Mr. Collins, late curator of the museum in Singapore, and Mr. Wray, curator of the Perak museum, have greatly contributed to our knowledge of the varieties of the *isonandra*, and of the methods of procuring and preparing the gum for the market. Through the representations of the latter the State Council of Perak a few years ago prohibited or considerably restricted the reckless felling of gutta trees in that State. The policy of *laissez aller* had prevailed too long in the three British Settlements and the other Protected States; there were very few trees left, and these only young. No effort has been made anywhere throughout Malaysia to propagate, cultivate, or plant the tree.

M. Sérullas' name is familiar as a frequent contributor to French scientific journals on the chemistry of gutta-percha. He has been at various times during the past ten years charged with a mission by the French Government to investigate the cultivation of gutta-producing trees and other tropical produce, with the object, as far as regards gutta, of introducing the tree into Cochin China and Algeria. Cuttings and seedlings were procured in and around Singapore, and their cultivation was attempted near Saigon, but the attempt was a failure. The *isonandra* refused to grow beyond 6deg. from the equator, and we have not heard of any Algerian plantation.

And here the writer may controvert two statements made in the extract from M. Sérullas' Paper. First: It is true that the leaves and branches of a young tree are richer in coagulated milk than those of an old tree, but it has yet to be demonstrated that this coagulated milk of the young tree contains the adhesive, elastic, and insulating properties of the milk of the older tree. Secondly: A gutta-percha tree is not valueless to a native from being *too old*. It is never too old to lend itself to "trunk working," by which we understand the process of felling and ringing described above.

About twelve months ago M. Sérullas formed a small company in Singapore to develop and work a process for the extraction, by chemical means, of the gum from the young branches, shoots, and leaves of the *isonandra gutta*. The chemical process followed was probably that "suggested" to M. Sérullas by M. Jungfleisch. A factory was established, branches and leaves were gathered in the adjacent jungle, and up to July of last year about 7lb. or 8lb. of gutta-percha were produced. This percha has been submitted to experts in England, and is found to be deficient in elasticity, to be short, brittle, having in excess the *resinous* gum which is common to most tropical trees. The Singapore Gutta-Extracting Company promised to revolutionise the supply of that commodity. A report on the "local industry" from the Governor of the Straits Settlements was considered by Lord Knutsford sufficiently important to be communicated to Kew, and was embodied, with other relevant matter, in the *Kew Bulletin* for September last.

It is to be hoped that M. Sérullas, M. Jungfleisch, and the Singapore Gutta-Extracting Company will pursue their investigations. They are in the right direction; but much remains to be discovered before "French capital can make the utilisation of the last resources of the Malay forests the object of a vast undertaking, capable of procuring for it great and immediate profits."

SOME "THOMSON" ELECTRICAL MEASURING INSTRUMENTS.

Although but few electrical measuring instruments are to be seen at the Crystal Palace, there is a very complete exhibit of "Thomson" apparatus, including an improved gold-leaf electroscope for the approximate measurement of potentials above 500 volts. The object of this instrument is to provide a convenient means of measuring approximately differences of potentials in cases where the accuracy of an electrometer is not required, and where its consequent expense would be a serious consideration. Only one narrow gold leaf is used, and this is attached by a clamp to a broad plate of brass. This brass plate is supported on a block of vulcanite from the roof of the case, and has a binding screw attached to it. The case of the instrument—with the exception of the front, which is of glass—is of metal, and the portion below the leaf is cylindrical in shape, so as to obtain from its inductive action a wide range of sensibility. A scale is engraved upon the back of the case, and another is placed in front close to the glass, in order that the deflections of the instrument may be read off without error due to parallax. A hinged frame is attached to the repelling plate, which folds down over the leaf to prevent damage during carriage, and when turned up it acts by repulsion as a guard which effectually prevents the leaf from touching the roof of the case at abnormally high potentials. The instrument may be used as a constant indicator to test the equality of the pressures between earth and each of the two primaries of a high-tension system.

Another piece of apparatus is an electric watt balance for the measurement of currents up to 10,000 amperes. These electric watt balances were designed in the first instance to meet the requirements for a standard balance to read up to 10,000 amperes. For this purpose it was not considered advisable to use the ordinary *idiostatic* "Thomson" balance, on account of the necessarily enormous proportions

Digitized by Google

which the movable beam would have, and the consequent limitation of range due to possible stiffness in the suspending ligament. The instrument was therefore designed on the plan of the composite balance, in which the main current passes through heavy copper conductors, while a small current of measured amount is passed through two coils of fine wire at each end of a movable beam in every way similar to that of the "Thomson" centi-ampere balance. The main conductor is shaped like a double rectangle, as shown in Fig. 1, and the current is conducted in by one electrode round three sides of the top rectangle, then down by a connecting piece at *a* round three sides of the bottom rectangle, and out by the other electrode. The beam, with its movable fine wire coils, is situated between the two rectangles, and its terminals are brought to two binding screws shown at *b*. The action when the current is passing is the same as in the other "Thomson" electric

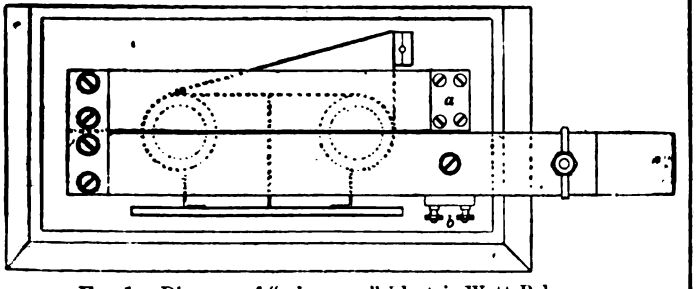

FIG. 1.—Diagram of "Thomson" Electric Watt Balance.

balances. The conducting rectangles are each made of a thick copper plate, with a slot about 0·5c.m. wide cut from the right-hand side up to within 9cm. of the left-hand end.

The instrument is, of course, a self-contained watt-meter, and when it is to be used as such extra resistances are provided for the fine wire circuit. The resistance of the fine wire coils is about 10 ohms, and the extra resistances provided are subdivided into coils of 400 ohms each, so as to permit of an adjustment of the instrument's constant from 50 to 2,000 watts per division of the scale. When the instrument is used as a standard ampere balance the current values can be obtained by dividing the watt readings by the electromotive force if a reliable voltmeter is available; but for very accurate working it is best to measure the actual current passing through the fine wire coils on an auxiliary instrument, such as a centi-ampere balance. By this method great sensibility can be obtained, as currents up to one ampere can be used, and so the constant of the instrument can be varied at pleasure from 0·1

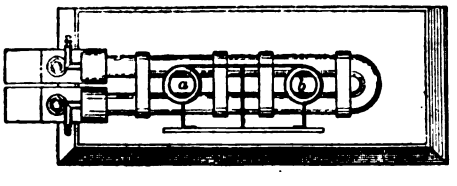

FIG. 2.—Diagram of "Thomson" Alternate-Current Kilowatt Meter.

ampere to 10 or 20 amperes per division of the scale; and thus a range of measurement from 0·1 to 12,000 amperes is provided. The balance, as described above, is intended for use with continuous current, and it is evident that an instrument of this kind, if used with alternating current, would require a special constant to suit different periods of alternation.

To suit cases where the testing is either on direct or alternating systems a different type of instrument, called the alternate-current kilowatt meter, with a stranded main conductor, is made. The instrument is shown in Fig 2, and it will be seen that the main conductor is of U shape, and passes under the movable coils. This conductor is made up of ropes of insulated copper wire, twisted together so as to form a cable with a hollow core. In order to correct any effect due to the induction of one arm of the coil upon the other the twisting is done in a very careful manner, so that the strands of the cable which are inside at the position marked *a*, are outside at the position *b*. The core of the cable is, as mentioned above, hollow, and brass tubes are passed up each arm of the U as far as the bend. The main object of these tubes is to prevent any deformation in the cable, but they also serve as a means of blowing air through to keep the conductor cool, if it should ever be necessary to use it for much heavier currents than those for which the instrument is primarily intended.

ON THE CAUSE OF THE CHANGES OF ELECTRO-MOTIVE FORCE IN SECONDARY BATTERIES.*

BY J. H. GLADSTONE, F.R.S., AND WALTER HIBBERT.

(Concluded from page 71.)

PART IV.—*Confirmations, Theoretical and Experimental.*

1. *Changes of E.M.F. with Two Similar Plates.*—In the discussion that followed one of our Papers at the Physical Society, Mr. Hibbert mentioned that if two lead plates are put into acids of different strengths, separated by a porous diaphragm, a voltaic current is produced on completing the circuit.† We have performed this experiment on two lead plates quantitatively, with reference to the E.M.F. produced, and have extended the observations to two peroxide plates.

The method of experimenting was as follows:—A divided cell was taken, in one compartment of which was placed sulphuric acid of about 0·2 per cent., in the other an acid varying from this strength upwards.

A pair of lead plates was tested in the weakest acid, in order to ascertain that when immersed in the same liquid they gave no appreciable E.M.F. One of the lead plates was then put into a stronger acid; and the E.M.F. between it and the other determined by the condenser method. This was continued up to a 98 per cent. acid, but, as the stronger acids act freely on spongy lead, the observations beyond 22·5 per cent. were made with two solid lead wires.

The results are given in the following table. The lead plate to the *weaker* acid behaved all through like a PbO_2 plate to the other, and it is, therefore, called the + plate.

Table VI.

Acid round + lead plate.	Acid round − lead plate.	E.M.F. in volts.
Per cent.	Per cent.	
0·2	0·65	0·036

"	48·0	0·164
"	57·5	0·204
"	85·5	0·247
"	98·0	0·266

A similar series of experiments was made with two peroxide plates. It is not likely, however, that the 99 per cent. acid had completely soaked into the meshes of the PbO_2. The peroxide in the *weaker* acid behaved like a lead plate, and is therefore called the − plate.

The results are delineated in the following diagram :—

If we consider Curve I. in Fig. 7—which shows the E.M.F. between two *peroxide* plates, one of which stands in sulphuric acid of only 0·2 per cent., and the other in strengths varying from that to 99 per cent.—we see at once that, while it rises through 0·589 volt, it is far from being a straight line. It rises very rapidly at first, then bends over and remains convex till about 18 per cent. is reached, when it becomes somewhat concave till about 57 per cent., after which it is tolerably straight.

If we consider Curve II., Fig. 7—which shows the E.M.F. between two *lead* plates, one of which is in the weak and the other in stronger acids—we find that it follows a similar course ; but the ordinates are only about two-thirds as large up to about 30 per cent., after which they are relatively much less.

In Curve II., Fig. 2, we have an experiment in which the peroxide plate was placed in various strengths of acid, while the lead plate was retained in acid of uniform strength, namely, 14 per cent. The observations are only from 6·5 per cent. to 81 per cent., but on comparing it within those limits with Curve I , Fig. 7, it will be at once seen that the curves are identical in form. They are also identical in the absolute amount of the rise. The difference between 6·5 per cent. and 81 per cent. in Curve II., Fig. 2, is 0·404 volt ; whilst in Curve I , Fig. 7, the difference is 0·401 volt.

In Fig. 3 we have also observations on a cell with the PbO_2 plate in various strengths of acid from 43·5 to 88·5 per cent., while the Pb plate remains in acid of 27 per cent. On comparing

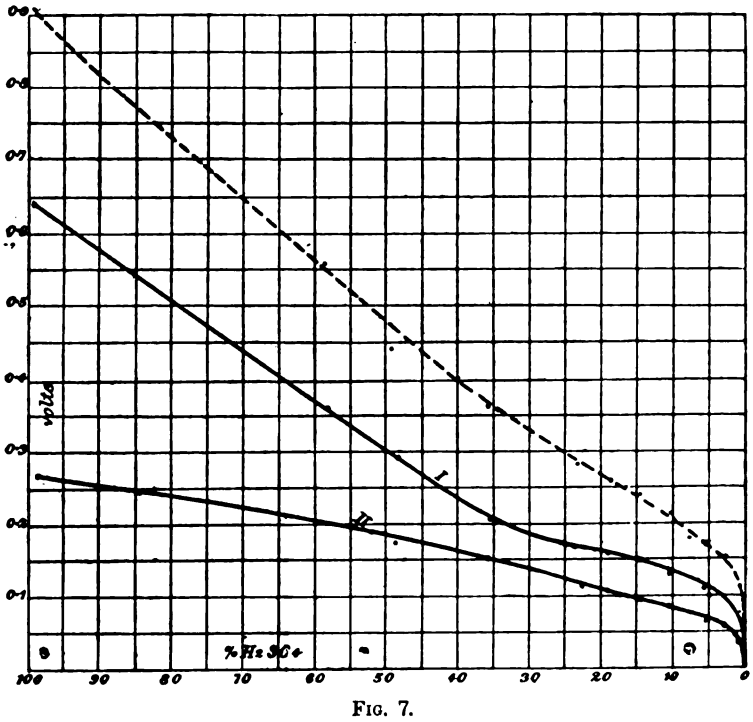

FIG. 7.

this with the similar portion of the curve in Curve I., Fig. 7, we find that in both instances we are dealing with a line which is very nearly straight. The rise of E.M.F. in Fig. 3 between the points mentioned is 0·307 volt, and in Fig. 7 it is 0·308 volt.

The close similarity both of the forms of the curves and the amount of the rise in each case shows that the causes of the phenomena represented in Figs. 2 and 3 are the same as those in Fig. 7, within the range of the experiments. There is, however, this essential difference in the experiments—that while in Figs. 2 and 3 we are dealing with a peroxide plate and a lead plate, in Fig. 7 we are dealing with two peroxide plates, and the results can be dependent only on the varying strength of acid. This, of course, is a strong confirmation of the theory we have propounded.

It is worthy of note that in the three experiments just compared together, the strength of the unchanged acid round the — plate was very far from being the same, varying, in fact, from 14 per cent. in Fig. 2, and 27 per cent. in Fig. 3 to 0·2 per cent. in Fig. 7. In other words, it does not matter what may be the starting point. This is just what might be expected if we are dealing merely with a differential result.

If we compare Curve I., Fig. 7, with the lower part of Fig. 3, we observe a general resemblance, but with well-marked differences. In each case there is the rapid rise at commencement, with the subsequent bend over and convexity. But in Fig. 3 the concavity has nearly disappeared. There is also another difference. The rise in this case between 6·5 per cent. and 49 per cent. is 0·251 volt, instead of 0·183 volt in Fig. 7.

These differences are easily explained. It will be remembered that the curve of Fig. 3 represents the variation of E.M.F. due to increasing strengths of sulphuric acid about the peroxide and the lead plate at the same time ; while Curve I., Fig. 7, represents the increasing E.M.F. due to increased strength of sulphuric acid solely at the $+PbO_2$ plate. In Curve II. of Fig. 7 we have, however, the E.M.F. due to increasing percentages of sulphuric acid round a – Pb plate. Now it has already been stated that increasing the sulphuric acid round the two plates acts in opposite directions in the two cases, so that the potential difference between them in any particular acid will be the arithmetic sum of the separate effects We have therefore added the two curves of Fig. 7 together and obtained the dotted curve, Fig. 7. It will at once be seen that this combined curve closely resembles the experimental curve in Fig. 3, the concavity having almost disappeared. The rise from 6·5 to 49 per cent. has become 0·27 volt, only slightly exceeding that of the curve in Fig. 3, namely, 0·25 volt.

We have thus resolved the rise and fall of E.M.F. during the charge and discharge of a cell into the two parts of which they are composed, and have determined them quantitatively.

2. *Confirmatory Evidence from Changes in Resistance.*—The general correctness of the conclusions arrived at in Part III. is supported, not merely by the known changes in E.M.F., but also by changes in resistance as given by Prof. Ayrton and his colleagues.

It is a matter of common knowledge that sulphuric acid varies very much in resistance according to its state of hydration ; that the resistance is least for acid of about 30 per cent., though not changing very widely between 15 and 50 per cent. ; and that if the acid become either weaker or stronger than these, its resistance rapidly increases. The following figures, calculated from Kohlrausch's results, will give an idea of the variation :—

Resistance of Sulphuric Acid Solutions.

% H_2SO_4.	Relative resistance.	% H_2SO_4.	Relative resistance.
2·5	6·73	50·0	1·35
15·0	1·33	71·0	3·79
30·0	1·00	95·0	7·29

Hence we should expect that if the acid against the working surfaces of the plates is being concentrated during charge, or greatly weakened during discharge, there would be a marked increase in resistance. This is exactly what is found to be the case. In the *Journal*, Vol. XIX., p. 590, is a diagram showing the very rapid increase of resistance during charge, the increase beginning when the E.M.F. (about 2·17) indicates, according to our theory, a strength of sulphuric acid against the working surfaces of the plates of somewhere about 50 per cent. : also showing that at the end of the charge "the resistance is five times as great as its minimum value."

This is particularly worthy of remark, because every other chemical change would tend to diminish, instead of increasing, resistance. The PbO_2 produced on the one plate, and the metallic lead produced on the other, are both much better conductors than the $PbSO_4$ which they replace.

On page 592 of the same volume is another diagram, showing that when the discharge of this cell was begun the E.M.F. had fallen from 2·30 to 2·06 volts ; and the resistance, which at the end of the charge was 0·0115 ohm, had fallen to 0·0038. We attribute both these falls to the same cause, namely, the reduction of the internal acid to about 30 per cent. Subsequently, the E.M.F. slowly diminished, while the resistance remained nearly the same for about five hours, when the E.M.F. more rapidly fell to 1·95 volts, and the resistance rose to 0·0055 ohm.

This is more than would be expected from the above table of resistances, but it must be remembered in this case that the other chemical changes—that is to say, the conversion of PbO_2 and Pb into $PbSO_4$ would also tend to increase, instead of diminishing, the resistance.

We do not lay great stress on precise numerical relations in the case of resistance, as the change in the strength of the acid at the working surfaces is only one of the factors, though an important one.

3. *Confirmation from Mr. Crompton's Experiments.*—During the discussion on the Papers by Prof. Ayrton and his colleagues, Mr. Crompton described two series of experiments which have a bearing on this subject.* In the first series some cells were discharged at rates varying from 11 to 66 amperes, and Mr. Crompton found that the ampere-hours delivered with a given range in potential difference fell from 300 to 125. He adds : In every

* *Jour.* Inst. Elec. Engineers, Vol. XIX., pp. 691, 692.

Digitized by Google

case the "form of the curve is very definite, the turn-down as soon as the E.M.F. falls to 1·8 being very marked."

This follows naturally, because at the higher rate of discharge the absorption of the acid in the pores has become much quicker, while the diffusion is scarcely affected, so that the weakening process goes on much faster. The critical voltage of 1·8 simply indicates that the internal acid has become very weak. Mr. Crompton's curves and remarks show clearly that the fall is independent of the amount of PbO_2 remaining on the plate.

In the second series of experiments thicker plates were used, and then he found a greater diminution of delivering capacity at the higher rates of discharge—in fact, it fell from 300 to 90 ampere-hours, and at the highest rate the fall began almost at once. This must be the natural result of the greater distance through which the entering acid has to diffuse.

4. *Confirmation from Thermo-Chemistry.*—It is possible to test the matter further by applying Lord Kelvin's law as to the relation between the E.M.F. of a cell and the thermal value of the chemical actions contributing to it. We hope to go into this matter more fully, and shall content ourselves at present with pointing out that the liquid in a secondary cell is a mixture, or a chemical compound, of two different liquids—sulphuric acid (H_2SO_4) and water, in varying proportions.

The simple problem is to determine what would be the voltage of a PbO_2 – Pb cell in which there was nothing but pure H_2SO_4.

From the thermo-chemical data which are before us we arrive at the value 2·627 volts. Our own determination, by means of the closest approximation which we could make to absolute H_2SO_4, is 2·607 volts.

With pure water only in the cell, the calculated value is 1·35 volts, whilst in an experiment we found 1·36 volts.

In determining the thermo-chemical values for mixtures of these liquids it is necessary to subtract the heat of dilution from the available energy. On doing this, the calculated and experimental numbers do not agree so well as those already given, until we come to the most prominent part of the curve at about 6 per cent. acid. The theoretical value at this point, as determined from the known heats of combination and dilution, would give 1·901 volts, the experimental value being 1·89 volts.

With lower figures than six per cent. it is evident that the change is not to be accounted for on thermo-chemical grounds, unless we admit a change in the chemistry as we approach pure water— a conclusion already drawn from other data.

It is now easy to understand the large potential difference required for charging an accumulator. The current has to do extra work in concentrating H_2SO_4 at the PbO_2 plate, and the energy equivalent to that work must be obtained from an increased potential difference. For a dyad gramme equivalent of H_2SO_4 concentrated from a 10 per cent. solution to 100 per cent. about 17,000 calories will be needed, and this = 0·37 volt. The calculated charging E.M.F. must, therefore, be at least 2·3 volts.

Part V.—*Consideration of other Suggested Causes of the Variation of E.M.F.*

As other causes have been suggested for the changes in E.M.F., it is desirable to consider how far they are in accordance with the known facts of the case. It is evidently possible that the phenomena may be due to a number of causes co-operating.

1. It might be supposed that the reduction of the E.M.F. in discharge is determined by the relative amount of lead peroxide, which is destroyed or covered over with sulphate of lead.

This is absolutely disproved by the experiments of Prof. Ayrton and his colleagues, which are graphically represented in Figs. 1 and 2, given on p. 661, Vol. XIX. of the *Journal* of Electrical Engineers. It will there be seen, from the determinations of the percentage of PbO_2 found on plugs removed, that the formation of the PbO_2 in charging, and the decomposition of it in discharging, is a fairly regular and continuous action. It gives no indication of the rapid changes at the commencement and termination of charging and discharging; while during the intermediate period, when there is little change of the E.M.F. for many hours, the rate of variation in composition is steady. This is indicated, as far as the discharge is concerned, by the dotted line in our Fig. 4, which is reproduced from the Paper by Messrs. Ayrton, Lamb, Smith, and Woods. (See also remarks on Mr. Crompton's experiments, *ante*.)

2. Planté considered that the exceedingly high E.M.F. observed for the first few minutes on joining up a completely formed cell, immediately after its removal from the charging circuit, was due to the gaseous hydrogen found on the Pb plate. Gladstone and Tribe,* while considering that this was possible, drew attention rather to the hydrogen occluded by the lead as a possible cause, but stated at the same time that this occluded hydrogen was exceedingly small in quantity. Frankland showed by a totally different process that it was practically *nil*.

* "Chemistry of Secondary Batts.," p. 48.

But hydrogen on one plate and oxygen on the other would not, under the conditions, account for as much as two volts, and this explanation is therefore inadequate.

3. Planté observed that a small quantity of lead peroxide is formed on the Pb plate during discharge; and Gladstone and Tribe found in this a reason for the state of electric equilibrium being approached before the peroxide on the PbO_2 plate is exhausted, and also for the fact that partly discharged accumulators give an increased current after repose ("Chem. of Sec. Batts," pp. 27, 28). This last action is attributed to the extreme rapidity with which the lead peroxide formed on the Pb plate must be destroyed by local action.

Mr. Robertson has recently added to this the observation that the formation of peroxide of lead on the Pb plate does not take place till the E.M.F. has fallen much below the normal value.*

We have already attributed the resuscitation of the E.M.F. on repose to the inflow of the stronger acid to the acting surfaces of the opposed plates, but we must look upon this formation of peroxide of lead, where it does occur, as contributing both to the reduction of E.M.F., and its resuscitation.

4. *Presence of some Form of "Active Oxygen."*—It is well known that electrolysed sulphuric acid contains some hydrogen dioxide, which is probably due to the decomposition of persulphuric acid by water.

Gladstone and Tribe showed that the presence of hydrogen dioxide in a cell must reduce the peroxide of lead—an observation confirmed by Robertson (*Proc. Roy. Soc.*, vol. I., p. 107).

Last June, both Mr. Robertson and Prof. Armstrong communicated Papers to the Royal Society, in which they attach great weight to the presence of peroxides in the electrolyte, as causing a loss of efficiency. As only abstracts of these Papers are published as yet, we cannot enter into any criticisms of their experiments. Mr. Robertson, however, in a lecture to the Society of Arts (*Jour. S. A.*. XL., p. 44), states that the "variations in E M.F. appear to depend on which plate hydrogen dioxide is found at. When present at the peroxide plate it causes a rise, but when diffused through the acid and present at the lead plate, it causes a lowering of the E.M.F."

We therefore made several experiments with the addition of hydrogen dioxide (both ordinary, and carefully purified from hydrochloric acid). Our arrangements admitted of adding the hydrogen dioxide to the electrolyte surrounding either the peroxide or the lead plate. Some of the determinations of E.M.F. were made by a condenser, and others by observing the current through an astatic galvanometer in series with a high resistance.

We generally obtained a slight reduction (about 0·02 of a volt), but only what might be fairly attributed to the dilution of the sulphuric acid.

It was still possible that some other form of "active oxygen" might accomplish what hydrogen dioxide had failed to do; and in order to determine whether these peroxidised products of electrolysis have really a different effect at the cathode and anode, we completed the charging of a pair of plates in a divided cell filled with 20 per cent. acid, and found that the "peroxides," or "active oxygen," existed only round the PbO_2 plate. We then reversed the plates in the compartments, so that the Pb plate stood in the liquid containing the peroxides (H_2O_2, persulphuric acid, &c.). One minute after stopping the charging current, and immediately before the reversal of the plates in the cell, the E.M.F. was 2·185 volts. After the reversal of the plates the E.M.F. was measured by potentiometer at intervals, the results being given in the following table:—

Time after reversal of plates.	E.M.F. in volts.	Time after reversal of plates.	E.M.F. in volts.
Minutes.		Minutes.	
1	2·163	12	2·063
6	2·081	15	2·055
8	2·078	22	2·044
10	2·066	45	2·031

There was evidently here no unusual fall in the E.M.F. The figures are embodied in the dotted curve of Fig. 1, and on comparing it with the fall for 18·5 per cent. acid they will be found so similar as to show that peroxidised compounds round the Pb plate had no visible effect. In each case the voltage evidently fell very slowly to a uniform value, and that value agrees very fairly with what we find for a 20 per cent. acid in Fig. 3. Through the kindness of Dr. H. Marshall, we were able to test the effect of adding some persulphate of potassium to the sulphuric acid in a cell about the PbO_2 plate, but without visible effect on the E.M.F. As far, therefore, as our own experiments are concerned, the E.M.F. appears to depend on the acid strength of the electrolyte,

* Robertson's report to Prof. Ayrton, &c., *Jour.* Inst. Elec. Engineers, Vol. XIX., pp. 670-675.

Digitized by Google

and not on the existence or the position of any peroxidised bodies dissolved in it.

ADDENDUM.

Although we did not undertake this investigation with the object of improving secondary batteries, there is one suggestion we should like to make—*i.e.*, the desirability of promoting diffusion as much as possible. We believe that this is becoming more and more the practice among those who make accumulators, and the previous considerations furnish three reasons for such a procedure.

It is well known that the accumulation of stronger acid at the lower part of a cell during its working is disadvantageous. This is believed to create differences of current density in different parts of the plate, and we have shown that it will also give rise to potential differences of fairly large value on each of the plates, and thus produce local action and the formation of lead sulphate. This inequality would be diminished if the diffusion of the acid could be promoted.

The fall of E M.F. at the close of discharge leaves a large fraction of the effective material not acted upon. This is mainly due to the weakness of the acid against the plates on account of the interstices being so much clogged ; and it would be counteracted to a considerable extent if the diffusion could be increased.

When a cell has been discharged at below 1·8 volts, there occurs the destructive action called "scaling." We are disposed to attribute this to abnormal chemical action arising from the very weak acid ; and if this be true, increased diffusion would in this case also act as a remedy.

Such increased diffusion might be obtained either by agitation or by heating, and we thought it interesting to try the effect of higher temperature on the output of our small cell. The following curve (Fig. 8) exhibits the result of one experiment :—

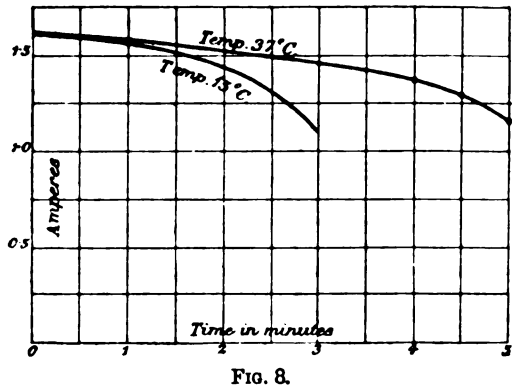

FIG. 8.

The discharge curves at the higher temperatures generally showed an output some 40 to 50 per cent. greater than those at the lower. But it is evident that the higher temperature would increase local action and the chemical action of the acid upon the spongy lead. This might be met by a reduction in the strength of acid, but we have not tested at what temperature and with what strength the advantage is at a maximum.

In addition to this suggestion, electricians will doubtless be able to make other useful applications of our conclusion that the changes of E.M.F. in a secondary battery depend on the strength of the acid that is against the working surfaces of the plates.

ELECTRICAL DISTRIBUTION BY THE NEWCASTLE-ON-TYNE ELECTRIC SUPPLY COMPANY.*

BY A. W. HEAVISIDE AND R. C. JACKSON, MEMBERS.

Preliminary.

The town of Newcastle is supplied with electrical energy by two companies, operating different districts, and distinct from one another. These are the Newcastle and District Company, using Parsons' turbines, supplying the southern and western portions of the town, and the Newcastle Electric Supply Company (the Company with which we are connected), supplying the northern and eastern portion. This Paper deals with the distribution of electrical energy by the Newcastle-upon-Tyne Electric Supply Company, Pandon Dene, it being thought that the members of the Institution would find interest in an account of the methods of working, and of the technical and financial results obtained during the first financial year of the Company's operations. The system employed is a high-pressure one of 2,000 volts, alternating current, with separate transformers in the consumers' premises. the price charged being 4½d. per Board of Trade unit. The Company was formed on January 7, 1889. Some questions having been raised upon legal points by the local authorities, the whole of 1889 was employed in negotiating the licence. These negotiations were more prolonged than usual, and it was not until the close of November that a provisional arrangement was entered into, enabling the Company to proceed with the street works in anticipation of the Board of Trade licence, which was not received until March 21, 1890.

Site.

Eligible sites for the establishment of a central station were found to be limited in number ; however, at Pandon Dene, some vacant land was eventually selected, which appeared to have some advantages in its favour. The business quarter is to the south, and the residential quarter to the north, thus facilitating the whole of the Company's operations being transacted from one point. The site is also alongside the sidings of the Blyth and Tyne branch of the North-Eastern Railway, which taps the Northumberland steam coal field. There is ample room for extension, as the Company's land occupies a space about 127ft. wide and 436ft. long, parallel with the railway. The absence of dwelling-houses in the immediate vicinity of the works avoids difficulties which might arise from the vibration caused by machinery in motion. Against these advantages must be set the want of cheap water for condensing purposes. The company's water is taken from the intermediate service of the local water company, the average cost per 1,000 gallons being 9·78 pence.

Buildings.

The dominant idea in laying out the station buildings was to so arrange them as to reduce any reconstruction to a minimum ; the erection of each successive section being carried out without interruption or disturbance to the plant already fixed. At the present time two sections have been built, enclosing a space 119ft. by 74ft. by 13½ft. high to the top of the girders. This space is covered by means of a light iron lantern roof, supported upon wrought-iron girders and cast-iron pillars, resting on concrete footings. The openings between the pillars are filled up with common brick, lined on the inside of the engine and dynamo-room, to about 7ft. 6in. high, with varnished pitch-pine. A brickwork partition separates the boiler-house, which is 74ft. long by 55ft. wide, from the engine and dynamo-room, 74ft. by 63ft. 6in. Two chimney-stacks have been built, one at either end of the main boiler flue, which runs along the boiler-house side of the partition wall. One chimney has a sectional area at the top of 30 sq. ft., and is 85ft. high ; the other chimney measures 23·5 sq. ft. at the top, and is 110ft. high. Great care had to be taken with the foundations, as the natural bed is no less than 75ft. below the present ground level, the intervening soil being made ground.

Contents of Buildings.

The station at present contains plant capable of a total output of 600 kilowatts, in the following units :—

1 250-kilowatt alternator ;
3 100-kilowatt alternators ;
1 50-kilowatt alternator ;

each machine being rope-driven by means of a separate engine. The year's operations dealt with in this Paper were, however, carried out by

3 100-kilowatt alternators, and
1 37½-kilowatt alternator.

The machinery in the station consists of :—

Three double-flued Lancashire boilers, manufactured by Messrs. Robey and Co., Lincoln.

General Particulars.

Working pressure, 120lbs. per square inch ; all plates of the best Siemens-Martin mild steel ; diameter of shell, 7ft. ; length of boiler, 28ft. ; boiler shell plates, $\frac{9}{16}$in. thick ; flue plates, $\frac{5}{8}$in. thick ; end plates, $\frac{3}{4}$in. thick ; number of flues, two ; diameter of flues, 2ft. 9in. ; 12 Galloway tubes ; heating surface, 750 sq. ft. ; grate area, 38 sq. ft. Two of these boilers have been fitted with Messrs. Bennis' mechanical stokers, and one of them with Messrs. Jas. Proctor's stoker. The figures of a test with these stokers will be given later in the Paper. N.B.—Two additional boilers have been fixed for the extensions now proceeding, fitted with Proctor's stokers.

Engines and Dynamos.

1 vertical compound engine by Robey and Co.

General Particulars.

Cylinders, 11in. and 18in. diameter, by 12in. stroke ; speed, 200 revolutions per minute ; fly-wheel, 6ft. diameter, grooved for eight 1in. ropes ; power, economical load, 75 I.H.P., with 110lb. steam pressure at the engine stop-valve. The engine is fitted with automatic expansion gear, and with Mever's adjustable cut-off on the L.P. cylinder. This engine drives a 37½-kilowatt Mordey-Victoria alternator with an E.M.F. of 2,000 volts effective at a speed of 650 revolutions per minute.

* A Paper read before the Institution of Electrical Engineers on May 26, 1892.

Digitized by Google

3 compound horizontal fixed engines by Messrs. Robey and Co.

General Particulars.

Cylinders, 16in. and 26½in. diameter, by 36in. stroke, fitted with the Rowland Richardson trip valve gear; 73 revolutions per minute; fly-wheel, 15ft. diameter, grooved for twelve 1¼in. ropes; weight of fly-wheel, 5 tons. N.B.—The fly-wheels are being weighted with an additional 5 tons each. Power, economical load, 175 I.H.P.; maximum working load, 240 I.H.P., with 110lb. pressure of steam on the engine side of the stop-valve.

These engines each drive a 100-kilowatt Mordey-Victoria alternator at a speed of 430 revolutions per minute. Each alternator is excited independently by means of an exciter connected direct to the alternator shafts. Another engine of the same class has lately been erected for the purpose of driving a 250-kilowatt Mordey-Victoria alternator.

General Particulars.

Cylinders, 19½in. and 33in. diameter, by 40in. stroke; speed, 70 revolutions per minute; fly-wheel, 17ft. diameter, grooved for 13 1¼in. ropes; weight of fly-wheel, 15 tons. Power, economical load, 400 I.H.P.; maximum load, 500 I.H.P.; with 110lb. of steam on the engine side of the stop-valve.

Water-Feed Apparatus.

One Gloster Duplex Pump, to throw 800 gallons per hour. Two Holden and Brooke's Exhaust Injectors, fitted with auxiliary live-steam nozzles, each delivering 600 gallons per hour at about 170°F. One additional injector, as above, for the plant extensions now going on.

Switch-Board.

Several forms of high-tension switches have been tried, but none have been found quite satisfactory. A permanent switch-board is now being designed to suit the Company's requirements.

Use of Plant.

For the light day and night load, the high-speed vertical engine is employed, the other machinery being brought into use as the service requires. The circuits, four in number, are coupled together or separated, as the load varies.

Distribution.

The electrical energy is distributed by means of four main circuits of concentric cable, insulated with vulcanised rubber, drawn into cast-iron pipes, of which nearly 10 miles have now been laid. The system adopted is that of one pipe, one cable, and means are provided at the street boxes by which the service may be treated either as a radial one or as a network, without disturbance to the insulation.

Cables.

The inner and outer conductors of the concentric cables are separated at each junction or lead-in, and are terminated by means of metallic washers, which are screwed down and clamped together on porcelain insulators. The system of mains is thus quite flexible, and changes in connections are made as easily and expeditiously as at a Post Office test box.

Street Boxes.

The street boxes are built of brick, set in cement, and protected from surface leakage by double cast-iron covers.

Transformers.

The transformers employed are, in general, those of the Elwell-Parker design, varying in capacity from 1 to 10 E.H.P., and are usually placed in cellars, upon the premises of the individual consumers. The Mordey, Kapp, Swinburne, and Tyne transformers are being experimented with.

Meters.

The "Shallenberger" is in general use, with some Aron, Ferranti, Thomson-Houston, and Frager meters under trial.

Working Results.

As already stated, the Company did not commence the supply of electrical energy until 1890, and then only experimentally. It was simply a year of construction and organisation. Commencing from January 1, 1891, by the end of the year the lamps installed equalled 431,000 watts, rising from 253,000 at the beginning of the year, or a mean of 342,000 watts. During the year 244,470 units were metered at the consumers' premises. The units metered at the station amounted to 327,821, showing a loss from all causes in distribution of 25·4 per cent. Dividing the total watt-hours sold during the year by the mean capacity in watts installed, we get a result of $\frac{244,470 \times 1,000}{342,000} = 714$ as the average lighting hours per annum. That is to say, our annual output was equivalent to running all the lamps installed for 714 hours—practically, two hours per day per lamp.

Character and Class of the Installations.

With the exception of the Post Office and the Public Library, the installations are small rather than large, there being no hotels and few restaurants, but mainly shops, offices, and private houses; the net result being a low load factor of 8·16 per cent. By the term "load factor" we mean the ratio of the units sold to the units that could be sold if all the lamps were always on.

Thus, $$\frac{\text{Metered watt-hours} \times 100}{\text{Mean watts installed} \times \text{number of hours in the year}}$$

$$= \frac{244,470 \times 1,000 \times 100}{342,000 \times 8,760} = 8{\cdot}16 \text{ per cent.}$$

Price.

The price charged by the Company has been described as the "phenomenally low one of 4½d per B.T.U." (less 5 per cent. discount). With gas costing only 1s. 10d. (less 10 per cent. discount) per 1,000 cubic feet, it is quite evident that whatever advantages the electric light possesses over gas, it would be difficult to obtain a higher price than 4½d. Believing that at this price a profit could be earned, we recommended the Company to charge this low figure, and we may say that our anticipations have been realised. The problem was, therefore, how to produce the unit at a low cost, and to obtain custom in sufficient amount to earn a fair dividend upon capital invested.

N.B.—It may be objected that the period of work upon which this statement is made is too limited to inspire confidence; but we venture to think that, once having overtaken our establishment charges, the commercial prospect will improve rather than the reverse.

Cost of Production: Coal.

The Company uses small steam coal, supplied and delivered by the Gosforth and West Moor Coal Company at the average price, over the year, of 5s. 10d. per ton.

Since 2,300 tons of coal were used, the quantity of coal burnt per unit sold amounted to $\frac{2,300 \times 2,240}{244,470} = 21{\cdot}074$lbs., at a cost of 0·663 of a penny.

It is to be noted that this coal bill includes all consumption for trial runs of new plant, various testing work, banking and making up of fires, steam heating to offices, and for all other purposes.

We consider that it would be interesting and of value if a relation could be established between the result as given above and the results—

1. If a standard Welsh coal had been used;
2. With water-tube boilers, burning small steam coal, with mechanical stokers;
3. With water-tube boilers, burning Welsh coal, both 2 and 3 being worked under the same conditions with respect to the load factor as in our own case.

For the purpose of facilitating such a comparison, we give analyses of Welsh coal and of that used by us—

——	Welsh coal.	Gosforth and West Moor.
Carbon	$14{\cdot}500 \times 0{\cdot}84$	$14{\cdot}500 \times 0{\cdot}649$
Hydrogen	$62{\cdot}032 \times (0{\cdot}046 - \frac{0{\cdot}06}{8})$	$62{\cdot}032 \times (0{\cdot}053 - \frac{0{\cdot}06}{8})$
Sulphur	$4{\cdot}032 \times 0{\cdot}015$	$4{\cdot}032 \times 0{\cdot}0124$
Ash, per cent.	4·9	13·44
Heat units	14,833	11,300
Theoretical evaporative efficiency in pounds of water from and at 212° Fahr., deducting ash in both cases	15·45	11·75
Or including ash	14·69	10·17

as the theoretical value per pound of coal, showing a difference in favour of Welsh coal of 31 per cent. It may here be remarked that the difference in cost between the best Newcastle coal and that used by us is generally about 50 per cent.

It is quite evident from the foregoing analyses that, in order to compare our results as to weight of coal per unit sold with London figures, a fair-sized divisor would be required. Our want of sufficient data does not enable us, unfortunately, to state what that divisor ought to be. We are in hopes of being enlightened on that point during the discussion on the Paper.

Water Account.

All the water consumed at the station for all purposes was measured by a Kennedy water meter, which registered 2,922,000 gallons for the year. To arrive at the amount of the water evaporated, a deduction of 10 per cent. is made to allow for such items as washing out and filling up of boilers, cleaning down lavatories, buildings, &c. The allowance being made, we have, as the total

Digitized by Google

water evaporated to steam, 2,629,800 gallons, or a water consumption per unit sold of $\frac{2,629,800 \times 10}{244,470} = 107{\cdot}5$ pounds, at a cost of 0·1053 of a penny per unit generated, or at the station = $107{\cdot}5 \times 0{\cdot}75 = 80{\cdot}63$ pounds.

The average evaporation of the boilers thus becomes—

$$\frac{\text{Pounds of water per unit sold}}{\text{Pounds of coal per unit sold}} = \frac{107{\cdot}5}{21{\cdot}074} = 5{\cdot}1\text{lb.}$$

We have obtained an evaporation of from seven to eight pounds of water per pound of coal with the boilers working under the best conditions; the difference, $7{\cdot}5 - 5{\cdot}1 = 2{\cdot}4$lb., is accounted for principally by banking of fires at times of low load and heating up of standing engines.

Oil.

Oil averaged 0·0014 gallon at a cost of 0·044 of a penny per unit sold.

Waste, Sweat Cloths, and Sundry Stores.

These work out at 0·055 of a penny per unit sold.

Repairs.

Repairs to buildings and plant at the station amount to 0 2480 of a penny per unit sold. This sum includes everything necessary to maintain the machinery at its full efficiency, and also to carry out some small alterations that experience suggested for the improvement of the plant.

Labour and Supervision.

It is found that at the period of maximum load the staff necessary to run three 200 H.P. engines and three 100-unit alternators consists of one station assistant, one engine-driver, and one stoker. Three sets of men are employed, arranged in shifts of eight hours each, with one hour overlap for cleaning, oiling, &c. The cost of the service, inclusive of proportions of the manager's and secretary's office charges, works out at 1·9462 pence per unit sold. The cost of all service external to the station over nearly 10 miles of mains, leads-in, transformers, meters, &c., is 0·2817 of a penny. To these figures have to be added the general charges, which amount to 0·6807 of a penny.

Summarising the cost, we have—

	d.	d.
Coal	0·663	
Oil	0·0440	
Petties	0·0579	
Water	0·117	: 0·8819
Repairs	0·2480	
Labour and supervision	0·8163	
External	0·2817	
General (rent, rates, taxes, law, sundry expenses)	0·6807	: 2·0267
		2·9086 per unit sold.

Capital.

When the capital account is closed for the works in progress, it is estimated that for each kilowatt installed an expenditure of £50 will have been incurred. This result will in all probability be reached by the end of the present year, when the plant erected will be capable of working at 600 kilowatts, or of dealing with 800 kilowatts wired, leaving one-fifth reserve plant.

Plant Efficiency.

We shall now consider some of the points in connection with the plant efficiency, it being always borne in mind that the results actually obtained are over a period of twelve months, with a mean load factor of 8·16 per cent.

Boilers.

With a view to the economising of labour, and to abate the smoke nuisance as far as possible, the boilers were fitted with mechanical stokers, as already stated. The following is a table showing the result of a test between the two classes of stokers now in use :—

Stoker Tests, July 5 and 18, 1891.

Description of firing.	Time in hours.	Gallons of water evaporated.	Coal consumed in pounds.	Pounds of water per pound of coal.	Per pound of combustible. From, and at 212 F.
Bennis stoker and bars	3¼	1,750	2,492	7·02	8·29
Proctor „ „	3¼	1,920	2,352	8·16	9·64
	—	9·7 %	6 %	16·2%	In favour of Proctor's stoker.

We have found the boilers supplied to us to be each capable of generating steam for 240 I.H.P. at the engine cylinders without undue forcing. The boilers are generally fed through exhaust steam injectors, assisted by auxiliary live-steam jets, the average temperature of the feed water being about 170°F.

Water.

The water used is of a medium quality, having 15 degrees of hardness.

Engines.

The engines are fitted with steam jackets in both the high-pressure and low-pressure cylinder. The steam, on its way to the low-pressure cylinder, passes through an intermediate receiver, where its temperature is raised, and probably some of the contained water re-evaporated to steam, by means of a coil of piping, through which a passage of live steam is maintained.

Dynamos.

The Directors have been much pleased with the satisfactory reports which have come in from the consumers regarding the steadiness of the light, which is in part due to the good government of the engines, and to the incidental advantage that the Mordey-Victoria alternators possess in the momentum acquired by the revolving field magnet. Improvements are being introduced as suggested by experience, and the 250-unit alternator now in course of erection is fitted with an outer bearing. The mechanical construction of the armatures also improves with each succeeding make. The oiling arrangements, by means of small pumps driven from the alternator shafts, have proved very effective.

Station Output and Efficiency.

The E.M.F. of the dynamos is measured by Cardew voltmeters, and the current by means of Evershed ammeters, the readings being taken every half-hour and posted in the engine-room day-book. The correctness of the various ammeters is checked from time to time by comparison with a Siemens dynamometer, which is, again, checked in the laboratory of the local College of Science. The principal data are as follows :—

Units metered at the consumers'	244,470
Station units	327,821
Loss in distribution	25·4 pr. cnt.
Total running hours at the station	7,504
I.H.P. hours	939,500
Average I.H.P. per hour $\frac{939,500}{7,504}$	= 125·2
Units per running hour (at the station) $\frac{327,821}{7,504}$	= 43·686
Average watts per I.H.P. per hour $\frac{43,686}{125·2}$	= 348
Weight of water per I.H.P. per hour, inclusive of radiation and condensation losses $\frac{2,629,800 \times 10}{939,500}$	= 27·91lb.
Average commercial efficiency of engines and dynamos $\frac{\text{Total E.H.P. for the year}}{\text{Total I.H.P. for the year}} \times 100$	= 46·6 per cent.

Parallel Working.

Trials have been made to work in parallel, with only a partial success. The trials called attention to the varying angular velocity of the engine fly-wheels, due to the early and quick cut-off of the trip valve gear. We hope to obtain successful results by increasing the weight of the fly-wheels, which work is now in progress; also by increasing the elasticity of the drive by the use of spring pulleys arranged on the principle of the transmission dynamometer, in place of the ordinary pulley. As a uniform turning effort is the end to be aimed at, we believe that the steps we are taking will accomplish that result.

Distribution.

The installations on the consumers' premises amounted to 431,000 watts on December 31st, 1891. The nominal transformer capacity supplying the above was 391,000 watts, or an excess of installed watt capacity to transformer provision of 9 per cent. The percentage of excess has been reduced by the recent extension of small shop-lighting, &c.; it had previously been run up to as high as 25 per cent.

The object we had in doing this was to keep the average transformer efficiency as high as possible, and at the same time to avoid undue fall of pressure in the service. This course may be safely carried out, if we discriminate between those consumers who burn all their lamps simultaneously and those who never by any chance do so. The average proportion of lamps lighted at any one time, to lamps installed, is about 45 per cent. Taking an extreme case, we have a proportion of 28 per cent. excess. We find the average lighting hours per annum of the various classes of consumers on the Company's mains to be as follows :—

Restaurants.	Shops.	Offices.	Private Houses.
1,563	459	499	344

As previously stated, the distribution losses from all causes average 25·4 per cent. over the year. The loss is incurred from

Digitized by Google

two sources—transformer and line losses. Weekly observations are taken, by means of Lord Kelvin's milliampere meter and a low-reading Siemens dynamometer, for the purpose of checking and comparing these losses.

Summary.

Summarised, the chief results embodied in this Paper are—

1. Load factor (as per definition)	8·16	per cent.
2. Loss in distribution	25·4	,,
3. Average lighting hours per annum	714	
4. Coal bill per unit sold	21·074	lb.
5. Water = 107·5 + 10 per cent. for water deducted for efficiency results	118·2	
6. Pounds of water evaporated per pound of coal, banking, &c., inclusive	5.11	lb.
7. Water consumption per I.H.P. hour	27·91	lb.
8. Engine and dynamo average efficiency	46·6	per cent.

General Conclusions.

Much discussion has taken place on the merits of the various methods of supply. We have had to consider the matter from a purely commercial point of view, having regard only to giving an efficient service, at the least cost, and quite without prejudice in favour of any particular system or mode of working.

That the results have been obtained by the use of separate transformers in the consumers' premises, without a secondary network, by machinery constantly running, with no storage except the coal heap, gives some ground for believing that in alternating-current distribution there exists a means of supplying the public with electric energy, and of meeting Parliamentary and other obligations, at a price which is satisfactory to the public, and affords investors a reasonable interest on their capital.

It may be stated to those interested in sub-transformer station distribution that the average losses in direct distribution over this year have been reduced from 25·4 per cent. to 19·5 per cent., and as the load increases it is hoped that further reductions will take place.

THE COUNTER ELECTROMOTIVE FORCE OF THE VOLTAIC ARC.*

BY F. STENGER.

The electrical phenomena of the voltaic arc have been the object of many investigations. The great difference of potential between the two electrodes, and the extreme constancy of this pressure in face of variations in the length of the arc, have led people to suppose that a counter electromotive force existed in the voltaic arc.

The researches on this subject have been carried by direct and indirect methods. The indirect methods, such as those of Von Larrgs, Arons, &c., are open to criticism, because they involve Ohm's law, and it is not admissible for one moment that the resistance of the gaseous column which composes the arc is independent of the current. The oldest of the direct methods was that of Edlund, who broke the main circuit, and about $\frac{1}{80}$th of a second later closed the circuit of the carbons through a galvanometer. Edlund obtained a deflection, which he attributed to the supposed counter E.M.F. Later on, Luggin employed an analogous method, which after laborious investigations yielded him a negative result, although the time which elapsed between the rupture of the arc and the closing of the shunt circuit was less than in Edlund's experiments. According to my own experiments Edlund's results were incorrect.

An objection may be made against Luggin's method, that if the condition of polarisation disappeared in less time than it took to close the derived circuit, Luggin's experiments demonstrated nothing. Lecher reinvestigated the matter, using another method.

In Fig. 1 D is dynamo connected to the carbons through the galvanometer G. The galvanometer needle was deflected against a stop by the dynamo current, but it could deflect freely in the opposite direction. The galvanometer, being in the main circuit, had to have a short thick wire winding. By joining the points *a* and *b* by a metallic conductor the dynamo was short-circuited, the difference of potential between the carbons became zero, and the arc was extinguished. If a counter E.M.F. existed in the arc, the galvanometer would have given a deflection. The result being negative, Lecher concluded that no counter E.M.F. existed.

This method was a decided advance on that of Edlund and of Luggin. The time which elapsed between the extinction of the arc and the making of the shunt circuit was zero, or excessively small. It may, however, be objected that the method is not very sensitive, since it requires a low-resistance galvanometer, and the resistance of the dying arc may be very high. My method only differs from that of Lecher by a detail which shows that the sensitiveness of the arrangement is amply sufficient.

Fig. 2 gives an idea of the arrangement. D was a flat-ring shunt-wound Schuckert machine, A a Kohlrausch galvanometer by which the normal current was measured, T a tangent galvanometer with the stop device mentioned before, R an additional resistance, B a battery of five accumulators, the negative pole of which was connected to the positive carbon. Two conductors connected the points *a* and *b* to a commutator.

While the lamp was at work the accumulators were being charged. The tangent galvanometer gave no deflection, its needle being jammed against the stop. By a turn of the commutator the dynamo was short-circuited, and being a shunt-machine the current

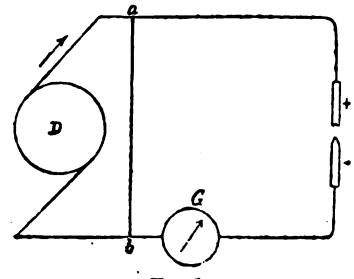

Fig. 1.

became zero. The difference of potential at the terminals of the lamp, therefore, fell very rapidly, and the arc disappeared. At the same instant the galvanometer gave a large deflection, sometimes exceeding 90deg. This experiment showed that the gaseous column continued to conduct, for a very short space of time, it is true, but sufficiently long to enable the current to effect a by no means sensitive galvanometer. The experiment did not, however, determine whether the deflection was due to the E.M.F. in question, or to the accumulators.

The accumulators were therefore removed, and the experiment repeated. The galvanometer did not then, on the short circuit being completed, deflect more than 0·5deg. to 1deg., a small deflection due to the spring of the stop.

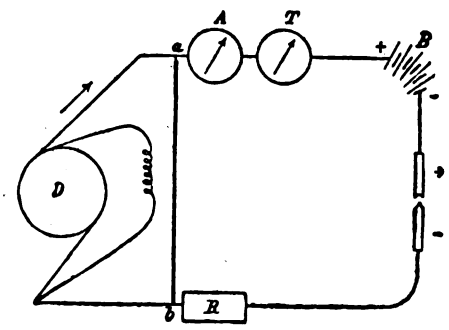

Fig. 2.

The following table gives a few of the observations. The experiments were only made when the arc was steady. The current and the difference of potential were observed immediately before the interruption of the main circuit; the length of the arc was estimated approximately.

Five Accumulators in Series.

Current.	Volts.	Length of arc (mm.).	Deflections.
17	40	3	55deg.
16	40	2	55 ,,
14·5	40	1	20 ,,
15	40	1	30 ,,
15	43	3	11 ,,
15	41	1	54 ,,
15	38	0·5	112 ,,
16	35	0·5	127 ,,

As would be predicated, the largest deflections corresponded to small arcs and large current. Deflections were also obtained when a certain time was allowed to elapse, and the temperature of the arc had become normal.

Thus, while at the moment of extinction of the arc the accumulators sent a large current through the gaseous column left by the arc, no discharge at all was obtained without the accumulators. It seems, therefore, to be proved in a definite manner that no counter E.M.F. exists in the arc.

THE ELECTRIC RAILWAY SCHEMES IN PARLIAMENT.

JOINT COMMITTEE OF LORDS AND COMMONS.

Another meeting of the Lords and Commons Joint Committee on the Electric and Cable Railway Bills for the Metropolis was held on Thursday, last week: Mr. Stansfeld in the chair.

Mr. DONALD MACMILLAN, of the firm of Messrs. Fowler and Co., solicitors, gave evidence as to the provisions in these Bills and in former Acts respecting the appropriation and use for tunneling of the subsoil beneath the roads and footways. There was nothing to prevent any owner who could establish damage claiming compensation.

Sir BENJAMIN BAKER and Sir JOHN FOWLER gave evidence as to the practicability of the undertakings from an engineering point of view; and explained that now that the efficiency of electric motors and cable traction had been demonstrated, one of the great difficulties which prior to 1884 had stood in the way of promoters had been removed; another difficulty being the want of sympathetic co-operation on the part of public authorities and the loading of the Bills with onerous clauses, which made the undertakings financially impossible.

Mr. BEACHCROFT was heard as to the desire of the London County Council that the proposed lines should be carried further into the outskirts so as to facilitate the transfer of the population from the congested districts of the metropolis.

The Committee adjourned until Monday, when they presented the following Report to the Houses of Parliament.

REPORT.

1. The Committee have met and have considered the matters referred to them, and have taken evidence submitted to them by the promoters of the various schemes including that of electric and other engineers, as well as that of representatives of the London County Council, of the Corporation of the City of London, of the agent and surveyor of Lord Portman's St. Marylebone estate, and of the Board of Trade.

2. The railway schemes that have been referred for their consideration are the following, viz.:—

The Great Northern and City Railway,
The Central London Railway,
The City and South London Railway,
The Waterloo and City Railway,
The Baker-street and Waterloo Railway, and
The Hampstead, St. Pancras, and Charing Cross Railways.

3. The Committee desire, in their report, to deal separately with the proposed Great Northern and City Railway.

4. The main objects of this scheme would appear to be to assist and relieve the great and growing local passenger traffic of the Great Northern line, and to afford it a new and direct access to the City.

5. It appears to the Committee that there can be no reason why this scheme should not be considered by Committees in ordinary course.

6. Further, the Committee are convinced that direct communication through London for the Main Railway lines north and south of the Thames, whether for the convenience of their country or their suburban passenger traffic, would be of undeniable utility. And they cannot doubt that the growing needs of those lines will, sooner or later, lead to the construction of one or more of such communications.

7. But the purposes which the proposed new lines, with the exception of the Great Northern and City Railway, appear intended and adapted to meet are of a different character.

8. They are required to relieve the overgrown passenger traffic along the chief thoroughfares, to provide for the natural expansion of London, and to check the congestion of our metropolitan population by facilitating cheap communication outwards to a circumference which tends constantly to recede.

9. More such lines of communication are required with existing suburbs; and there is growing need of their extension still further into the country, in order to meet the increasing necessity for the removal of portions of the population to a greater distance.

10. The lines now in question will afford some portion of this much-needed accommodation; and where they terminate in or near the open country they are practically certain of further extension to meet the needs of a growing and spreading population.

11. It does not appear to the Committee, with regard to any of these lines, that their construction would prevent that of other lines which the necessities of London may from time to time require, and they see no reason, therefore, for advising the postponement of the consideration, in ordinary course, of any of these Bills.

12. With regard to the question whether underground railways worked by electricity or cable traction are calculated to afford sufficient accommodation for the present and future probable traffic, the Committee report that the evidence submitted to them was conclusively in favour of the sufficiency and the special adaptability of electricity as a motive power for the proposed underground tubular railways, whilst the method of cable traction appears also to be of recognised utility, especially in the case of steep gradient lines.

13. The proposed routes appear to be fairly satisfactory, considered as an instalment of the more complete accommodation necessary to meet the constantly increasing needs of London.

14. As to the terms and conditions under which the subsoil should be appropriated, the Committee report that in the case of private property, not under the public streets, it appears to them to be desirable that the companies should be allowed to acquire a wayleave, instead of purchasing the freehold of the land, subject to the terms of the Lands Clauses Acts as to compensation.

15. In the case of public streets the Committee think it expedient that the companies should be empowered to pass under the streets at sufficient depth without payment of compensation for the wayleave. In consideration of such free passage the Committee advise that the companies should be put under obligation to furnish an adequate number of cheap and convenient trains.

16. The evidence submitted to the Committee on the question of the diameter of the underground tubes containing the railways, has been distinctly in favour of a minimum diameter of 11ft. 6in.

17. The Committee have directed the minutes of evidence taken before them, together with an appendix, to be reported.

PARLIAMENTARY INTELLIGENCE.

The London County Council (Subways) Bill.

In the Select Committee of the House of Lords engaged in considering the provisions of the London County Council (Subways) Bill on Wednesday, clause 11, which deals with the regulation of water, gas, and electric wire mains carried through the subway, was under consideration. Six electric lighting companies petitioned against the Bill, objecting to have their wires subject to the control of the County Council instead of the Board of Trade, and claiming to remain, as hitherto, under the general order of 1869. The Earl of Crawford was examined in support of the petitioners' case, and stated that he was concerned in the investigation which resulted in the subdivision of London into districts for the purposes of electric lighting, and in the inquiry held by the Board of Trade in 1888. It was at the time thought that it would be best to carry the electric lighting wires in subways. There were then only four subways in existence, one of which was the Southwark subway. The objection to having the mains for electric lighting and gas and water in one chamber was the danger of flooding and of explosion from fire when the pipes were under repair. It would, in his opinion, be desirable that the Board of Trade should have control of the mains in the subway and not the County Council. Sir F. Bramwell, adviser to the electric lighting companies, also gave evidence in support of the objections of the petitioners.

The Committee decided that the petitioners had proved their case, and that they should be exempted from the provisions of the Bill, with the exception that if Clause 11 were so altered that the Board of Trade should be the controlling authority then the electric lighting companies should not be exempt.

LEGAL INTELLIGENCE.

Western Counties and South Wales Telephone Company (Limited) v. Bournemouth and District Electric Supply Company (Limited).

In the Chancery Division, on Friday, the case of the Western Counties and South Wales Telephone Company v. Bournemouth and District Electric Supply Company again came before Mr. Justice Chitty. This was a motion which asked that a writ of sequestration might be issued for contempt of Court against the Bournemouth and District Electric Supply Company for wilfully disobeying an order of the Court directing that they should be perpetually restrained from working or using their electric lighting system, apparatus, and works in the town and neighbourhood of Bournemouth, in such a manner as to injure or interfere with the plaintiff's exchange system. Mr. Byrne, Q.C., who appeared for the defendants, asked for further time to consider the fresh affidavits which had been filed. His Lordship granted the application.

Pepperell v. City and South London Railway Company.

The plaintiff in this action, which came before Mr. Justice Wills on Tuesday last, was a traveller, and he sued the defendant railway company to recover damages for personal injuries. His case was that on July 22nd he was about to travel from Kennington Station to Stockwell, and went to Kennington Station. He had never travelled by the electric railway before, and complained that the platform was so badly lighted that he could not see the permanent way. As a consequence he fell on to the line, and severely bruised and injured himself. He also complained that there were no porters on the platform to assist passengers. The defence was that the station was sufficiently lighted, and that the accident happened solely through the negligence of the plaintiff. The plaintiff appeared in person, and Mr. W. Graham appeared for the defendants His Lordship gave judgment for the defendants, with costs.

BOOKS, &c., RECEIVED.

"Report to the Governors." April, 1892. City and Guilds of London Institute.

"A Treatise on Electricity and Magnetism." By James Clerk Maxwell. Vols. I. and II. Third edition. (Oxford: Clarendon Press.) Price £1 12s.

TRADE NOTES AND NOTICES.

TENDERS INVITED.—The Corporation of Hanley invite tenders for the execution of works required for the supply of electricity within the borough, in accordance with the Hanley Electric Lighting Order, 1891. Plans and particulars may be obtained from Mr. Joseph Lobley, borough engineer; and tenders must reach Mr. Arthur Challinor, town clerk, before noon on Monday, June 20. Further particulars appear in our advertisement columns.

——The Corporation of Hull require tenders for supplying and erecting a switch and distributing board. Tenders are to be in by Thursday, June 17th. Further particulars will be found in our advertisement columns.

—— Tenders are invited for the supply to the General Post Office of red fir telegraph poles, and for creosoting them. Forms of tender can be obtained from Mr. Charles E. Stuart, Controller of Stores, Telegraph-street, E.C., to whom tenders must be sent by noon on June 24th. Further particulars appear in our advertisement columns.

—— The Great Western Railway Company invite tenders for the purchase of old telegraph materials, consisting of gutta-percha wire, copper battery mud and silver battery plates. Forms of tender may be obtained of the Secretary at Paddington Station, or of the Storekeeper at Swindon; and tenders must reach Mr. G. K. Mills, the Assistant Secretary, Paddington Station, by Wednesday next, the 1st prox.

—— Tenders are invited for the electric lighting of the Rue de la Station, the Place de la Station, the Grand Place, and the theatre in Louvain, Belgium. Tenders must reach the Hotel de Ville, Louvain, by July 1st.

PLANT FOR SALE.—Messrs. Wheatley Kirk, Price and Goulty announce in our advertisement columns that they have for sale a 10-arc light installation, comprising two 30-light Thomson-Houston continuous-current dynamos, a 100-H.P. Babcock-Wilcox boiler, 58 Thomson-Houston double carbon arc lamps, a 12in. Marshall vertical steam engine, &c.

—— Our advertisement columns contain an announcement of some electric plant for sale, comprising a 400-light compound and a 100-light shunt excelsior dynamo, a 5 H.P. motor, and 51 E.P.S. cells. Further particulars of "Electric," care of Eason and Son (Limited), Dublin.

APPOINTMENT VACANT.—An engine driver, to attend to the electric light installation, is wanted at once, at the Smallpox Hospital Ships, Long Reach, near Dartford, Kent. The wages are 25s. per week, with board, lodging, washing, and uniform. Forms of application may be obtained at the chief offices of the Metropolitan Asylums Board, Norfolk House, Norfolk-street, Strand, W.C., where they must be delivered, duly filled up, by 10 a.m. to-morrow (Saturday).

CITY OF WESTMINSTER ELECTRICAL SYNDICATE (LIMITED).—At meetings of the members held on April 13th and May 4th it was resolved and confirmed that the syndicate be wound up, and that Captain E. I. Bax, 32, Victoria-street, Westminster, S.W., be the liquidator.

CHANGE OF ADDRESS.—The address of the Civil and Mechanical Engineers' Society will be in future 12, Delahay-street, Westminster, London, S.W.

INTERNATIONAL OKONITE COMPANY (LIMITED).—Mr. G. R. Murray, 93, Hope-street, Glasgow, has been appointed agent in Scotland for the Company.

THE LONDON ENGINEERING EXCHANGE.—This exchange will be declared open officially in the Exchange Room of the Jerusalem, Billiter Buildings, E.C., on Tuesday next, the 31st inst.

MESSRS. J. AND W. WEEMS.—We have received from this firm their newly-issued catalogue of special machinery, including their patent hydraulic pipe presses for the lead trades. Amongst Messrs. Weems' specialities is their machinery for producing one to four lead pipes or rods at one operation, and covering with lead telegraph and telephone cables or electric light conductors in long lengths, and also leads for accumulators. Many of the leading electrical firms are users of Messrs. Weems' machinery.

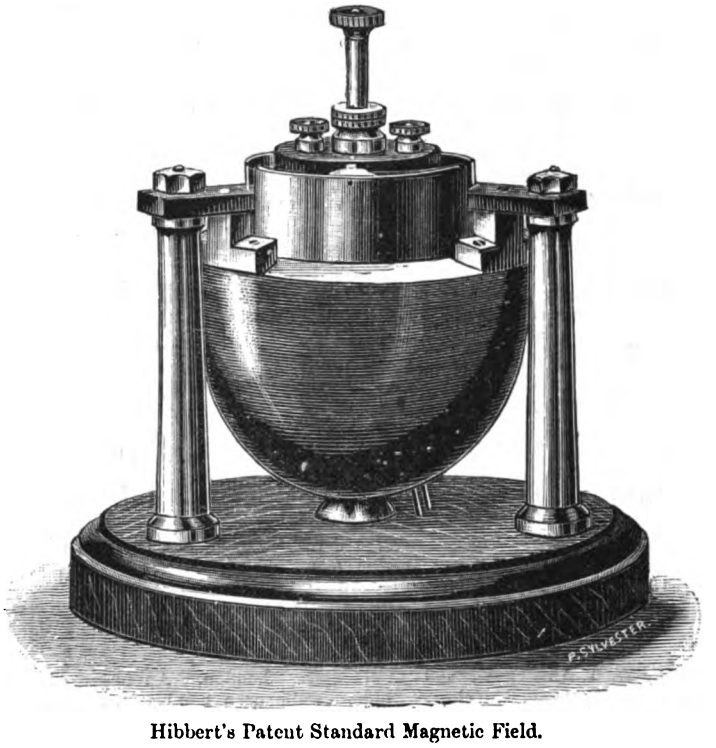
MR. W. S. SARGEANT.—The new electric launch "Myionu," built by Mr. Sargeant, is now complete, and has left for Windsor. Her length is 35ft., beam 5ft. 8in., draught aft 18in. She was built for Captain Homfray, of the Horse Guards. Her hull is constructed of mild steel, and is fitted with a handsome teak cabin. The electrical power consists of 40 E.P.S. accumulators, with high-speed propeller connected up direct with the armature shaft, and rotating at about 650 revs.

MESSRS. SHEETON AND PAGE.—This firm have just installed a complete plant for 50 lights in the offices of the Commercial Telegram Bureau, Tokenhouse-yard, E.C.

GLASS PIPES.—An American journal is responsible for the statement that Mr. R. G. Guptell, glass manufacturer, of Anderson, Ind., U.S.A., has rediscovered the lost art of casting glass pipes, which is claimed to have been carried on by the ancient Egyptians. A factory has been erected at Pendleton, and the first glass castings have been successfully made.

WRAY ELECTRICAL ENGINEERING COMPANY.—We are notified that this Company has commenced business at the Soho Electrical Works, Thornton-road, Bradford, and that the Company has several installations in hand, including the lighting of Rufford Lodge for Mr. C. B. Crawshaw. The firm are manufacturing electricians and electrical engineers, and are manufacturers of, amongst other specialities, the "Soho" Patent Dynamo. Mr. Cecil Wray has the management of the business.

MAGNETIC STANDARD.—Hibbert's patent standard magnet, which was described in *The Electrician*, Vol. XXVIII., p. 178, is being manufactured by Mr. C. Bowron. The instrument consists of a



Hibbert's Patent Standard Magnetic Field.

steel magnet enclosed in an iron bowl. A coil of wire is allowed to drop in the air gap between the magnet and the bowl. The real use of the instrument is to give a standard electromotive force of a uniformly impulsive character.

MESSRS. WOODHOUSE AND RAWSON UNITED (LIMITED).—This firm has opened a branch office and show-room at 22, Rue Lafitte, Paris, which will be the chief depôt for their French trade, and all communications regarding same should be addressed to Mr. E. Kenealy, the manager there. We understand that Mr. E. H. Cadiot no longer represents the firm in France.

"BIBLIOTHECA ELECTROTECHNICA."—Under this title Mr. F. von Szczepanski, of St. Petersburg, has prepared a very useful compilation of the chief English, American, French, and German electrical books and publications. The list gives the size, price, and name of publisher, and the entry in the list is made in the language in which the book is written. Where the book is translated from the original this is clearly shown. The little work is published here by Sampson Low and Co., at 1s. 6d.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

May 3, 1892.

8,291. J. W. EWART. London. Improvements in arc lamps.

8,294. J. C. B. TAYLOR. Holloway. The electric light advertisement.

8,367. J. R. HUGHES. London. Improvements in incandescent electric lamps.

8,385. W. F. TAYLOR. Croydon. Improvements in electricity meters.

8,397. F. A. HASELWANDER. Manchester. Improvements in the method of and apparatus for transforming and distributing electric currents.

Digitized by Google

8,399. J. W. PARAMORE and H. THEAKER. Sheffield. Electrical or galvanic braces.
8,408. I. CLIFFORD. London. Improvements in electric incandescent lamps.
8,452. A. CHAPMAN. London. Improvements in driving certain machines by electro-motive power.
8,463. C. COERPER. London. Improvements in electric arc lamps.

May 5, 1892.

8,493. R. WHITEHEAD and A. DOXEY. Sheffield. Improved telephone transmitter.
8,507. C. MILES. Bristol. Electric time-check, call-bell, and registering apparatus.
8,529. W. MOSELEY. London. Improvements in galvanic batteries.
8,535. W. FOWLER. London. Electrical hose signalling apparatus.
8,537. W. E. LANGDON. Derby. Improved electric light switch.
8,556. O. PATIN. London. Improvements relating to alternating-current electric machinery.
8,572. H. BECKMANN, E. BECKMANN, and J. SCHMITT. Glasgow. An improved galvanic element.

May 6, 1892.

8,576. E. H. P. HUMPHREYS. London. Improvements relating to the measurement of electrical currents.
8,611. R. C. KRUSCHKE. London. An improved electric alarm for show cases.
8,638. T TOMLINSON. London. Improvements in electric mains.
8,642, E. F. CARPENTER. London. An improved holder for holding shades or globes of electric, gas or other lamps.

May 7, 1892.

8,663. H. F. JOEL. London. Improvements in the cores of electro-magnets for motors and other purposes.
8,706. S. A. MOORE. London. Improvements in electrical fittings, such as ceiling roses, and cut-outs.
8,720. W. T. GOOLDEN and S. EVERSHED. London. Improvements in electric meters.

May 9, 1892.

8,743. A. SHIELS. London. Improvements in couplings for electric wires.
8,745. B. M. DRAKE and J. M. GORHAM. London. Improvements in switches for electric light work.
8,768. W. P. THOMPSON. Liverpool. Improvements in and relating to mechanically driven alternating dynamo-electric machines combined with an electric lamp (H. S. Hellebrandt, Austria).

May 10, 1892.

8,805. H. N. PRENTICE. London. Improvements in dynamo-electric machines and electric motors.
8,837. T. ARMSTRONG and C. HASCALL. London. An improved non-consumable electric light candle or a non-consumable candle for arc lamps.

SPECIFICATIONS PUBLISHED.

COMPANIES' MEETINGS.

Taunton Electric Lighting Company (Limited).

A meeting of the shareholders of the Taunton Electric Lighting Company (Limited) was held at the Municipal Hall, Taunton, on Thursday week, to consider what steps shall be taken with respect to the disposal of the works to the Town Council. It appeared that on the previous Monday the Managing Director of the Company had an interview with the special committee of the Town Council with regard to their taking over the works, when it transpired that even if the Town Council obtained a Provisional Order, it would not come into operation until July, 1893, whereas the Company in its present position felt they could not carry on the business until then, unless some arrangement was made in reference thereto. It was suggested that the Town Council should allow the Company to continue working under their supervision, or that the Town Council should rent the works until July, 1893. It was necessary that something should be done promptly, as one customer was waiting to be supplied with 100 incandescent lights, and the Company were unable to supply them owing to want of capital. The result of the interview was that it was agreed to write the Local Government Board, to ascertain whether they would be willing to receive a joint deputation from the Corporation and the Electric Light Company, to discuss the question of carrying on the works until the Provisional Order could be obtained. It was stated at the meeting that no reply had been received to that letter, and after considerable discussion the following resolution was passed :—

"The shareholders advise the Directors to continue the negotiations for the sale of the Company's undertaking to the Town Council for the sum of £9,300, as from July 1st next."

New Shanghai Electric Company (Limited).

The annual meeting of shareholders of this Company was held at the offices, 14, Szechuen Road, Shanghai, on April 14th; the Chairman, Mr. J. Beattie, presiding.

The CHAIRMAN said: Gentlemen, I propose to tell you as much as I can regarding the Company's position generally, and thereby anticipate your questions and thus expedite the proceedings. I hope that you feel satisfied with the report and accounts sent you some time ago, and with your consent we will consider them as read. You will see that we have had no difficulty in maintaining the previous 7 per cent. dividend, after writing off a liberal sum for depreciation. The attempt made last year, to obtain subscribers for the remaining Tls. 50,000 (about) of the authorised capital, fell through, partly owing no doubt to the commercial depression then prevalent. This was indeed unfortunate, as we could easily employ the whole of the additional sum in fulfilling the numerous applications made for incandescent lighting. Outside installations, in steamers, &c., are progressing steadily; but I may point out that, as regards materials sold, no profit is charged on fittings to consumers supplied from the Company's mains. All the plant is in good order and condition, and it will be satisfactory to you to know that Mr. Prentice, whose opinion I am sure you think perfectly reliable, has assured us that the machinery could not be replaced at anything like the present valuation shown in the accounts. The time has now come when the ordering of further machinery is absolutely imperative, and we have here, already drawn out, a telegram ordering what is simply indispensable without any further delay, but which we have determined to keep over till after this meeting, so that you should be quite posted up to date regarding the actual position of the Company. The amount involved in this order is only about Tls. 15,000; and if the shareholders between them do not underwrite this sum, which will not be called up for several months, the Directors will have to fall back on other provisional arrangements they have made. We are aware that the quoted price of shares makes the issue of more capital at par a difficult matter; in our opinion, however, the position and prospects of the Company do not warrant the shares being at a discount, but that is a matter entirely beyond our control, and for this additional outlay, in which we are quite prepared to take our share, we can only appeal to the public spirit of our shareholders, and we hope not in vain. The charge proposed for Directors' fees looks heavy, but it covers a long period, during which three retired and the three remaining members of the Board (amongst whom the fees will be divided) have had arduous and trying duties to perform.

The Directors' report and accounts recommending a 7 per cent. dividend were then adopted, and the retiring Directors and auditors were re-elected.

After some feeling remarks from Mr. Douglas Jones as to the able services rendered by Mr. Porter, their secretary, a vote of thanks to the Chairman terminated the proceedings.

Elmore's French Patent Copper Depositing Company (Limited).

An extraordinary general meeting of this Company was held at the Cannon-street Hotel on the 21st inst., Major Charles Jones in the chair, when the following extraordinary resolution, which was passed at the general meeting of the Company held on the 22nd ult., was submitted for confirmation as a special resolution :—

"That the capital of the Company be increased to £400,000, by the creation of 100,000 new shares of £3 each. Such new shares shall be called Preference Shares, and shall be entitled to priority on a distribution of assets, and shall also be entitled, out of the profits available for distribution in each year, to a preferential dividend of 10 per cent., and to a further dividend of 5 per cent. after a dividend of 15 per cent. has been paid on the existing shares of the Company, which shall in future be called Ordinary Shares."

The Secretary (Mr. J. SHURMER) having read the notice convening the meeting,

The CHAIRMAN observed that, as no dissent was expressed at the last meeting to the proposal, there was no necessity for him on this occasion to give any explanation with reference to the matter. He might, however state that very good reports had been received from France, where everything connected with the Company's affairs was going on well. A circular letter of the Company had been issued since the 22nd ult., and the replies already received had been very satisfactory. Trial and other orders had been sent in from a large number of houses, including some of the best firms in France. These orders were now being executed, and the work was progressing in a very satisfactory way. He concluded by proposing the confirmation of the resolution as above.

Sir JAMES MACKENZIE seconded the motion, when a short discussion followed, and, in reply,

Digitized by Google

The CHAIRMAN said that any engineer or manufacturer would tell them that it took a considerable time to get to work first of all, even if they had the orders, and then it would take a considerable time to work the factory up to the full output. They had to get the whole organisation in order. They had only been able gradually to bring the tanks into operation: and what they reported at the last meeting—M. Secrétan's report—was the correct statement, namely, that there were 80 tanks, turning out about 100 tubes a day, at work.

A SHAREHOLDER: And that is so now?

The CHAIRMAN: Yes. The output is approximately perhaps a little better than it was then; but the actual output of tubes for sale has not increased very materially, for the simple reason that we have been occupying some of the tanks, which would otherwise have been making tubes for sale, in coating mandrils with copper, and in making duplicate mandrils, so as to be in a position to go on steadily with the work, and not have to stop the tanks while waiting for mandrils. We are turning out about nine to ten tons a week.

A SHAREHOLDER stated that a letter of the Chairman of the Company, dated the 1st of January, informed the shareholders that he had started the works, and that they were capable of turning out 80 tons a month.

The CHAIRMAN stated that the view taken by the shareholder of the letter in question was mistaken. It was not 80 tons a month, but approximately 80 tons a week. That, however, was what the factory was erected ultimately to produce; it was 300 tons a month. The only report that the Chairman of the Company made was that he had started the first two tanks, showing that the works were in order; but that was a very different thing from working the factory at its full output.

A SHAREHOLDER: I understand that you now produce about ten tons a week?

The CHAIRMAN: Yes, and we shall go on increasing that. M. Secrétan is pushing on as fast as he can, and he is gradually bringing more tanks into use every week. In answer to other questions, the Chairman, continuing, said that if any shareholder would call at the offices, the Secretary would be very glad to give him information as to the returns which were periodically received by the Company from France. With regard to the preference capital, the amount they had allotted was between £24,000 and £25,000, and the Board were, in addition, making arrangements, under certain conditions which they saw no difficulty in fulfilling, for placing another £40,000.

A SHAREHOLDER: Why do we want so much preference capital as you propose?

The CHAIRMAN stated that they only took power to issue £120,000. This was to pay for the extra expenses of the factory and to provide working capital to go on with. The original working capital was not sufficient to carry them on during the time they had been a Company, and to pay for the large factory which had been erected.

A SHAREHOLDER inquired who was responsible for the excessive liabilities which had been incurred.

The CHAIRMAN stated that the outlay had been authorised by the Directors. They had power to borrow money up to half their capital, and the Board had exercised their authority in the interest of the shareholders.

A SHAREHOLDER: When will you come to turn out 300 tons a month?

The CHAIRMAN said that he could not give an accurate answer to such a question, but assured the meeting that all possible speed would be made to arrive at a full output.

The resolution was then put to the meeting and was confirmed *nem. con.*, the meeting afterwards separating.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

CAMBRIDGE ELECTRIC SUPPLY COMPANY (LIMITED).—This Company was registered on May 18th, with a capital of £50,000, in £10 shares. The objects for which the Company is established are to carry on the business of electrical engineers, electrical contractors and undertakers for the supply of electricity for lighting, transmission of power and any other purposes; and to promote, support and obtain any Acts, Provisional Orders, licences and other authorities necessary or desirable for the carrying out of any of the objects of the Company, and in particular to take a transfer of the powers, duties and liabilities granted to and imposed upon the Mayor, Aldermen and Burgesses of the Borough of Cambridge, by the Cambridge Electric Lighting Order, 1890. The first Directors are William Bond, Sir Benjamin C. Browne, Gerard B. Finch, the Hon. Charles A. Parsons, John B. Simpson and George Whitmore.

MISCELLANEOUS.—EDWIN HAMPTON (LIMITED), electrical and general engineers, iron, and brass founders, &c.; capital, £10,000, in £5 shares.—PUBLIC WORKS TRUST (LIMITED): constructors of all kinds of public works in Italy and elsewhere.

ANGLO-GENERAL ELECTRIC LIGHT COMPANY (LIMITED) (IN LIQUIDATION).—A notice has been filed announcing that at a meeting of this Company held on May 10, 1892, for the purpose an account was furnished, showing the manner in which the winding up of the Company had been conducted and the property of the Company disposed of. The Company was registered on November 8, 1881, with a capital of £24,000, in £1 shares, to acquire by purchase or otherwise and to work all or any of the inventions of, and the patents and patent rights granted or to be granted to, Leonard Jules Bouteilloux and William Laing, both of Paris, for improvements in means or apparatus for producing and applying electricity for lighting, motive power and otherwise, for improvements relating to dynamo-magnetic electro machines, for improvements in electric lamps, and all other matters and things in any way or manner connected with electricity and the means of producing, transmitting, distributing and applying the same. By special resolution passed and confirmed in April, 1883, it was determined that the Company was to be wound up voluntarily, and Mr. Charles F. Reynolds, of 13 and 14, King-street, Cheapside, E.C., was appointed.

BATH ELECTRIC LIGHT COMPANY (LIMITED).—This Company has been dissolved under Clause 7 (4) of the Companies Act, 1880 (43 Vict., ch. 19), by notice in the *London Gazette*, dated May 10, 1892. The Company was registered on March 21, 1889, with a capital of £25,000, in £10 shares.

BENHAM AND FROUD (LIMITED).—The annual return of the above-named Company, made up to the 11th inst., was filed on the same day. The Company was registered on July 29, 1885, with a capital of £50,000, in £10 shares. At the time of making up, 2,907 shares had been taken up, and, according to the return, all have had the full amount called, thus resulting in the payment of £28,852. 10s., and leaving £217. 10s. in arrears.

CHLORIDE ELECTRICAL STORAGE SYNDICATE (LIMITED).—The statutory return of the above-named Company, made up to May 4, 1892, was filed on the 20th inst. At the time of making up 48 founders' and 11,927 preference shares had been taken up, and a call of £1 per share had been made, resulting in the payment of £9,965. 10s., and leaving £2,008. 10s. in arrears.

ELECTRIC "SUN" LAMP AND POWER COMPANY (LIMITED) (IN LIQUIDATION).—A notice has been filed notifying that a meeting has been called, and has received an account showing the manner in which the winding-up of the Company had been conducted and the property of the Company disposed of. The Company was registered on June 26, 1882, with a capital of £200,000, in £5 shares, to purchase the patent rights of an electric lamp called the "Lamp Soleil" for the United Kingdom and elsewhere, and the right of manufacture and use of certain other inventions connected with electricity, and to carry on the business of an electric light and power company in all its branches. By special resolution, passed September 25, 1885, and confirmed October 15, 1885, it was determined that the Company should be wound up voluntarily.

ORIENTAL TELEPHONE COMPANY (LIMITED).—The annual return of the above-named Company, made up to the 11th inst, was filed on the 16th inst. The nominal capital is £300,000, divided into 225,000 ordinary and 75,000 vendor's shares of £1 each. Of these, 223,494 ordinary and all the vendors' shares have been taken up, of which, 3,494 ordinary and the vendors' shares have been issued as fully paid. Upon the remaining 220,000 ordinary shares 11s. per share has been called, and all calls have been paid.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended May 22nd were £767, as against £768 for the corresponding period of last year, being a decrease of £1. The total receipts to date, from January 1st last, amount to £16,696, against £15,375 in the corresponding period of 1891, being an increase of £1,321.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to appoint special settling day in, and to grant a quotation to £98,400 additional Four per Cent. Mortgage Debentures.

ELECTRICITY SUPPLY CORPORATION (LIMITED).—Application has been made this week for £70,000 in 700 £5 per cent. debentures of £100 each, redeemable at par in 1900. The interest is payable half-yearly, and the debentures may be paid off at any time at £105 after six months' notice; £10 is payable on application, and the balance on allotment. The lists closed yesterday for London, and this day (Friday) for the country.

ISLINGTON AND GENERAL ELECTRIC SUPPLY (LIMITED).—Applications are invited by the Exploration Company (Limited) for 45,000 £5 shares in the above Company, payable 10s. on application, 10s. on allotment, and the balance in sums of £1 on June 30, August 31, October 31, and December 30, 1892. The share capital of the Company is £250,000, and the present issue is for £225,000. Included in the Directorate are Sir Frederick Abel, K.C.B., F.R.S., and Mr. R. W. Wallace, of the Westminster Electric Supply Company. The Engineers to the Company are Prof. A. B. W. Kennedy and Mr. V. B. D. Cooper; the Consulting Electrician is Mr. Gisbert Kapp; the Secretary is Mr. R. McA. Inglis, and the offices of the Company are situated at 5, Victoria-street, Westminster, S.W. The prospectus states that the Company has obtained Provisional Orders for supplying the electric light in the parishes of Camberwell and Islington, these Orders running for 42 years from 1889. As both these districts are very populous, it is anticipated that a very large business will be done by the Company, more particularly as they have been successful in opposing applications by competing companies for Board of Trade Orders for the parishes represented. The first station to be erected is to be on the low-tension system, and a contract has been entered into with Messrs. J. E. H. Gordon and Co., (Limited) by which they agree for the sum of £144,000 to provide a site for the first station, and erect and equip two stations in Islington with a capa-

Digitized by Google

city of 37,000 lights burning simultaneously, to lay mains, and to pay the cost of the flotation of the Company up to allotment, &c., &c. Under this arrangement, the first station is to be completed within eight months from the entry of the contractors upon the works. Tenders will be invited for the erection of a station at Camberwell. The subscription lists will open on Monday next, the 30th inst., and close on or before Tuesday, the 31st. Further particulars will be found in our advertisement pages.

RUSTON, PROCTOR AND COMPANY (LIMITED).—The Directors, in the balance sheet made up to March 31, 1892, say that the trading results for the year show a balance of £49,271 10s. 10d., from which has been deducted depreciation of plant and machinery and Directors' remuneration, leaving £44,983 8s. 10d. Out of this there has been paid the interest on the debentures and the interim dividend of 5s. per share, paid October 1, 1891, leaving a net balance of £26,233 8s. 10d. The Directors propose the payment of a dividend of 10s. per share, making, with the interim dividend, 7½ per cent. for the year.

SPANISH NATIONAL SUBMARINE TELEGRAPH COMPANY (LIMITED).—The numbers are announced of 86 bonds of £100 each of the Six per Cent. Mortgage Debentures, for payment at par on and after June 30th next.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended May 20, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,803.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 733.—Vol. XXIX. FRIDAY, JUNE 3, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

A full report of the annual general meeting of the Electrical Trade Section of the London Chamber of Commerce will be found elsewhere in the present issue. Although many matters of considerable importance were discussed, the attendance was, as usual, somewhat meagre, not more than 15 per cent. of the members of the Section being present. The election of Major Flood Page as Chairman will, we think, commend itself to the industry at large, and the influx of a little new blood in the shape of the election of Mr. Alexander Siemens as one of the Vice-Chairmen shows that the Section is alive to the danger of getting into a groove. It is to be hoped that the prompt appointment of a Committee to consider the electric traction and telephone question will render the formation of yet another Association unnecessary. As several speakers remarked, the tendency of the electrical industry to split itself up into minute sections is greatly to be deprecated.

There was evidently an Oliver Twist spirit abroad at the Institution of Electrical Engineers last week. In spite of the array of figures with regard to last year's working of the Newcastle Electric Supply Company, most of the speakers "asked for more." Some additional data were obligingly supplied on the spot by Messrs. Heaviside and Jackson, and others were promised for the *Journal*. The discussion, though brief, was one of the best we have had this Session, being, with the exception of a momentary lapse into an interchange of views as to the relative merits of open and closed circuit transformers, rigidly confined to corroboration or confutation of statements advanced in the Paper just read, and it was not, as is too often the case, a mild conversation upon things in general.

Mr. Crompton was of opinion that the figures given by the authors of the Paper bore out his contention that alternate-current high-pressure distribution is more or less an expensive luxury; and he proceeded to asperse the character of alternators for efficiency, which resulted in a challenge from Mr. Mordey—which was promptly accepted—to run representative dynamos of either kind upon a bank of lamps at the Crystal Palace, the machine which ran the larger number for a given indicated horse-power to be adjudged the victor. On the other hand, as Mr. Preece justly observed, alternate-current companies, owing to their comparatively low capital expenditure, can afford to spend more money on distribution than low-pressure concerns. In the case of the Newcastle Electric Supply Company the total capital expenditure comes out at 30s. per lamp installed, made up as follows: Buildings and land 2s. 8d., station plant 13s. 1d., switchboard 7d., pipes and boxes 4s. 7d., mains 4s. 7d., loose plant 4d., transformers 4s. 2d.

Sir David Salomons was apprehensive lest the figure of 4½d. per B.T.U. charged at Newcastle should get abroad without qualification, and showed that taking gas in London at 3s. against 1s. 10d. at Newcastle, the equivalent price of electricity in London worked out at practically 8d., so that Londoners had nothing to complain of. Difficulties have arisen in Newcastle in regard to working alternators in parallel owing to the irregular running of the engines. To remedy this defect, the authors of the Paper proposed heavy flywheels or springs placed between shafting and pulley; a correspondent this week opines that the valves should be looked to.

The research forming the subject of the interesting Paper by Messrs. Edser and Stansfield, which was read at a recent meeting of the Physical Society, was suggested by the calls which have been made upon the Kew Observatory for the examination and certification of so-called non-magnetisable watches. Ever since dynamos have been in commercial use those employed about them have either protected their watches by an iron case or sheath or have had alterations made to the movements. The commonest watches often escape injury altogether, and trouble generally is found in the magnetisation of the balance-wheel of compensated watches. But in low-class watches the compensation is often a mere dummy, and the time-keeping qualities are in no way affected by replacing the balance by a plain one of gold or brass. The hair-spring occasionally gives trouble, and the coils may even stick together after exposure to a strong field; but a phosphor bronze spring, though difficult to adjust, behaves very well. M. Paillard has used alloys of palladium, but manganese steel is obviously the best material for the purpose. The lever also may with advantage be made of manganese steel, but as the ruby pallets prevent metallic contact, it does not give much trouble.

It is to be hoped that either Messrs. Edser and Stansfield will continue their researches, or that the Kew Committee will make some investigation as to the strength of field which

Digitized by Google

is likely to temporarily affect or to permanently injure watches of various makes and qualities. At the Paris Exhibition of 1881 we experienced the inconvenience of the magnetisation of a watch, and after demagnetising it by spinning, replaced the compensated balance by a wheel of plain gold. A phosphor bronze spring was tried, but gave bad results. Although the watch contains an unusual amount of steel work in the chronograph motion, it has never been affected since by proximity to dynamos. The balance-wheel is arrested by eddy currents in a powerful field, and the watch as a whole is strongly magnetic, but goes very well considering that it is not compensated.

Apart from its bearing on the injury to watches, the investigation of the stray field of dynamos both as regards direction and strength by means of the instrument described in the present number would be of considerable interest. Curves of the direction of the lines of force in the neighbourhood of a dynamo are in themselves very instructive, showing clearly how and where leakage takes place. But by means of this instrument another set of curves of equal strength of field might be added, intersecting the former everywhere at right angles. Theoretical diagrams as given in the plates at the end of Maxwell are easy enough to draw, but the actual disposition of the field round a dynamo is very difficult to guess.

In a short article which we publish this week, Mr. Carl Hering proposes to use the term "ampere-centimetre," or some equivalent expression, as the unit number of lines of force, and gives reasons which show that the dimensions of the unit of magnetic flux are the same as those of an ampere multiplied by a length. Although, however, it may be perfectly justifiable, as far as dimensions are concerned, to express a number of lines of force as so many ampere-feet, it is quite erroneous to assume that the number of lines of force produced by the current flowing in a circuit is proportional to the number of amperes multiplied by the number of feet of wire composing the circuit. The error in Mr. Hering's argument lies in his assumption that his quantity K is constant. As a matter of fact this ratio varies very much for different sizes and shapes of circuit, whether there is any magnetic substance like iron in the neighbourhood of the conductors or not.

The number of lines of force produced by a current C in any circuit is equal to the product L C, where L is the coefficient of self-induction of the circuit. L is a quantity whose dimensions are those of a length, so that Mr. Hering's first contention is quite justifiable; but in order that the number of lines produced may be proportional to the current multiplied by the length, it is evidently necessary that the self-induction of a circuit of given length must be the same however the wire is wound, and this cannot be even roughly true in the general case. With certain restrictions, however, it is quite possible that the proportionality holds; and when these conditions are fulfilled, the simple rule, that the flux of lines produced is proportional to the magnetising current multiplied by the length of wire conveying it, becomes a useful working formula.

On investigation we find that the following conditions are necessary in order that the number of lines of force in a magnetic circuit may be proportional to the number of ampere-feet of magnetising wire. The magnetic circuit must be very good, as in a dynamo machine in which little magnetic leakage occurs, and, if the number of lines per ampere-foot is to be the same for different dynamos, the iron must be of the same quality and magnetised to the same state of saturation, so as to have the same permeability, and the dynamos must be of the same type, that is, the ratio of the length of the magnetic circuit to its diameter must be constant. It is fortunate that these conditions are all very nearly fulfilled in the manufacture of any given type of machine.

The Patin dynamo which we illustrate in another column presents several features of interest, though there is nothing new in principle. Remembering that the inventor was until recently in partnership with Mr. Ferranti, it is not surprising to find that there is some resemblance to the well-known dynamos of which the Deptford station contains such fine examples. On the other hand, the stationary armature and revolving magnets recall the Mordey alternator; but, as far as can be judged from the illustration which we reproduce from *L'Industrie Electrique*, the French dynamo is inferior in mechanical design to either of the English types to which we have alluded. The armature appears to be mounted on a sleeve, which rides on the revolving shaft. The sleeve must fit the shaft closely in order that the clearance may be kept constant, and no adequate provision is apparent for taking the weight of the armature or preventing it from rotating.

The waste of valuable time which always takes place in the Law Courts when an electrical case comes on for trial, owing to the need of conveying to the Judge a clear idea of the meaning of a few technical terms, is only too well known; and any means of reducing the great cost of this elementary instruction is well worthy of the attention of both plaintiffs and defendants. An energetic and apparently successful effort in this direction has been recently made in the American Courts during the hearing of the important "Feeder" and "Main" case, brought on by the Edison Company. In order to save time, quite a collection of physical apparatus was prepared with the view of illustrating each step in the argument. Series and parallel systems of distribution were illustrated by working models, each consisting of a closed system of water circulation. Coloured water was made to flow through glass pipes by means of a rotary pump representing the dynamo, and waterwheels were placed in circuit, either in series or in multiple arc, to represent the lamps or motors absorbing the electrical power. Pressure tubes were also attached at different parts of the circuit to represent the distribution of voltage. Models of a more elaborate kind were also shown in illustration of the various feeder systems of distribution with which the

Digitized by Google

case was concerned; and our contemporary the *Electrical Engineer*, of New York, has fully illustrated them in a recent issue. While these latter models refer chiefly to a special lawsuit, and are unlikely to be wanted again, the former are of a much more general character, and, for some years to come, it seems likely that a little money spent in constructing them would be more than repaid by the saving of time they would effect in the hearing of electrical cases in English Courts. Models of machinery are common in our Law Courts, and an elaborate model representing a particular form of distribution was a feature of the Lane-Fox case; but elementary models of series and parallel distribution and the like would be of great value.

Society of Arts.—The annual *conversazione* of this society will take place at the South Kensington Museum on Wednesday evening, June 29th.

Personal.—We understand that Mr. Guy C. Fricker is about to terminate his engagement with the Gülcher (New) Electric Light and Power Company.

Interurban Telephony.—The Paris-Tours telephone trunk line was opened to the public last month, and the Paris-Bordeaux line is daily expected to come into operation. Telephonic communication between Odessa and Nicolaieff (80 miles) has been successfully established.

Private Art Collections in London.—The *Art Journal* for this month contains an interesting account of Sir John Pender's fine collection of pictures. Details of the history of many of them, with several engravings, are given; together with sketches of Sir John Pender's house in Arlington-street.

St. Saviour's District Board.—This Board has received a statutory notice from the City of London Electric Light Company intimating that they intend to apply to the London County Council for permission to erect a wharf on Bankside. The Board have, however, decided to strenuously oppose the application.

Bournemouth.—We may mention in connection with the action (a full report of which will be found in another column) brought by the Western Counties and South Wales Telephone Company against the Bournemouth and District Electric Supply Company, that the mains are principally concentric, with some Silvertown pairs in branches.

Civil Service Commission.—The Civil Service Commissioners will, on June 22nd, hold an examination for the post of Second Assistant to the Lecturers at the Royal Artillery College (20—25). The date specified is the latest at which applications can be received. They must be made on forms to be obtained, with particulars, from the secretary, Civil Service Commission.

Royal Society.—Among the Papers down for reading yesterday were the following:—Major Darwin, "On the Method of Examination of Photographic Objectives at the Kew Observatory;" Lord Kelvin, P.R.S., "On a New Form of Air-Leyden, with Application to the Measurement of Small Electrostatic Capacities;" Dr. J. Larmor, "On the Theory of Electrodynamics as affected by the Nature of the Mechanical Stresses in Excited Dielectrics;" and Major Hippisley, "On Current Curves."

Obituary.—The death is announced of Mr. T. Prime, head of the oldest existing electro-plating firm in Birmingham. In 1842, Woolrich, who in the working out of his ideas had received special facilities at Messrs. Prime's plating works, patented an electro depositing dynamo. This machine, which was employed for a long time by Messrs. Prime—who undertook the working of Woolrich's patent—was presented by them a few years ago to the Corporation of Birmingham, and is now deposited in the museum at Aston Hall.

The City of London Electric Lighting Company and the New Telephone Company.—At the last meeting of the Court of Common Council the Chairman of the Commission of Sewers was asked whether it was true that the Company carrying out the lighting of the City by electricity had given permission to a telephone company to lay their own tubes down at the same time without first asking the consent of the Commission of Sewers. Mr. Treloar replied that he did not know of any pipes being laid except those of the Electric Lighting Company.

Dr. J. A. Fleming's "Alternate Current Transformer."—Owing to the large demand for Dr. J. A. Fleming's Alternate Current Transformer," a third issue of Vol. I. is now ready This volume consists of 500 pages, and is accepted as a text-book on the subject in the Universities and Colleges of Great Britain, the Colonies, and America. Volume II. is in the press, and will be published about the 13th instant. It will consist of more than 600 pages, and will be very fully illustrated. Both books form part of *The Electrician* Series.

The London-Paris Telephone.—Speaking at a meeting of the shareholders of Reuter's Telegram Company, on Wednesday, a report of which will be found elsewhere, Admiral Sir John Hay said that the London-Paris service had involved important structural re-arrangements at the premises in Old Jewry, chiefly in order to secure a room impervious to outside sounds, as only the most expert telephonists were able to catch the sound of the voice coming over such a long distance, and he mentioned incidentally that 8,000 words were heard and recorded within three-quarters of an hour.

The National Telephone Company and its Sheffield Subscribers—At a meeting of telephone subscribers at Sheffield on Monday last, the report of the Subscribers' Committee was presented, and passed after some discussion. It was decided to form an Association of Sheffield Telephone Subscribers. The tariff, as accepted, was practically that published on p. 84 of our last issue. The Committee stated in their report that the National Telephone Company "pledged themselves fully that Sheffield should have the best system that could be given to any centre, even if it involved the adoption of the twin-wire and metallic circuit system."

The Electric Lighting of the City.—After the distressing condition of the main thoroughfares of the City, consequent upon the operations of the City of London Electric Lighting Company, say the *City Press*, it is pleasing to know that their *employés* managed to do a great deal of work in spite of the congested state of the traffic in the streets through which they passed. Trenches were cut at the rate of from 800 to 900 yards per week, and the total quantity cut up to the 14th ult. exceeded 60,000 yards, leaving about 20,000 yards to finish. On the same date 3,630 yards of distributing mains had been laid down, and over 6,000 connections had been made. This was a little more than a fourth of the applications which the Company had on its books.

The Waterloo and City Railway Scheme.—The South-Eastern Railway Company intend, it is understood, to offer a strenuous opposition to the passing of the proposed Waterloo and City Railway. In the petition upon which this Company will appear, after setting forth that the proposed railway will be constructed practically between the same points as those "now efficiently" served by their existing line to Cannon-street, they proceed to allege that the proposed railway is, in fact, projected by the London and South-Western Railway Company, or, at any rate, is introduced solely in the interests of that Company, and is, in effect, an extension of their railway into the City of London. Such a railway, they contend, Parliament would never sanction if it were openly promoted by the South-Western Company, who have, they say, received immense benefit from their railway without contributing one penny either to the cost of the railway or of the Cannon-street Station. The promotion of this railway by indirect means is, they contend, inconsistent with good faith on the part of the South-Western Company, and they submit that it would be a great injustice to enable that Company, by means of the proposed railway, to divert from their system a large amount of traffic which now passes over the most costly part of their railway.

The Electric Railway Promoters and the Proposed Mansion House Subway.—The subway scheme suggested by Mr. H. H.

Digitized by Google

Bridgman in 1885 to facilitate the traffic at the much-congested Mansion House centre is likely to be carried out in the near future free of expense to the ratepayers. At a special meeting of the Commissioners of Sewers, on Wednesday last a report of the Finance and Improvement Committee was unanimously adopted, recommending the proposal of the Electric Railway promoters to construct a central station underneath the open space in front of the Mansion House, Bank of England, and Royal Exchange, on condition that a series of public subways be constructed thereat at the sole expense of the railways. The Bills will, therefore, go before the Parliamentary Committee untrammelled by any objections under this head by the City authorities. The access to the subways will be by means of staircases from the public way—descending about 8ft.—at the corner of the Union Bank, in front of the Royal Exchange, by the London, Liverpool, and Globe Insurance Office, by the side of the Mansion House, at Mappin and Webb's corner, and by the Safe Deposit building, and will all communicate with a circular corridor, 15ft. wide, embracing the several points mentioned, lighted by electricity, from which the station will be entered and access gained to the railway level some 60ft. beneath the surface of the street.

The Fire at Scott's Restaurant.—Writing to the *Morning Post* of Wednesday, Mr. E. C. de Segundo says:—

So much misconception seems to have arisen as to the interpretation of my evidence at the adjourned inquest on the above fire that I will ask you to grant me a little space in your paper to correct the distorted views which have been taken of the matter owing to ignorance of the more important facts of the case. The idea seems to have gained ground that my opinion was invited generally as to the cause of the fire, and that the tendency of my evidence was to the effect that electric light in a house is a source of danger and risk of fire. These views are inconsistent with the facts of the case, with the intention of my evidence, and with the finding of the jury. You will doubtless recollect that the question of the electric light as a possible cause of the fire arose only at the end of the first inquest, some of the jury stating that, as the fire had broken out in that part of the premises lighted by electricity, they thought that the opinion of an expert should be taken on the possibility of the electric light having been the cause of the fire. The Coroner then adjourned the meeting for a week, and invited my opinion as an expert in the matter of wiring of houses for the electric light, on the following point—Whether or not it is possible for defects in the system of putting up electric light wires to cause a fire, and if so, whether or not there were evidences of any such defects having existed in the system of wires as erected at Scott's Supper Rooms. I will ask you to note that I was not called upon in the first instance to discover the cause of the fire, but to report upon the possibility of a connection between the electric wiring in a house and a cause of fire, with particular reference to the fire at Scott's. I found certain defects which would never have existed had the work been done under competent supervision, and which I mentioned in my report and in my evidence; but my answer to a juror, which really sums up my opinion on the matter (and which was reported in *The Standard* of the 21st ult.), was as follows:—A juror: Do you consider that the fire was caused by the electric light? Answer: I think it is distinctly possible, but I find no definite tangible evidence to that effect. This, I think, should sufficiently dispose of the wrong impressions which seem to have arisen. . . .

Thunderstorms.—On Wednesday last week the midland and eastern counties were visited by a severe thunderstorm. At Epworth a house was badly damaged. At Derby the old parish church of St. Werburgh's, which is shortly to be rebuilt, was struck, and one of the pinnacles of the tower was displaced. At Gainsbro' the signal-box on the Great Northern Railway at Lea was struck, the instruments were damaged, and the lightning conductors fused. The discharge melted wires and set fire to wood work in no less than five places. Near Whitby a lad was killed by lightning as he was crossing the railway just outside a village. At Retford, portions of the wooden sheds, which are in course of erection in connection with the forthcoming Notts Agricultural Society's Show, were struck, and four of the workmen injured. At Rockley, a servant was struck by lightning. In London, on Thursday last week, the alarm-bell communicating with the fire-post in East-street commenced ringing violently in the Old Kent-road Fire Station. The members of the brigade turned out, but found that the lightning had struck the wire and started the bell. On Tuesday last a storm burst over Bishop Auckland, during which a fatal lightning stroke occurred at Shildon. On Wednesday a violent thunderstorm occurred at Bristol, and caused serious damage to University College. The lightning struck a large stone figure weighing 5 cwt., which was destroyed. An immense block of 2 cwt. fell through the electricians' room, smashing the roof and destroying the electrical apparatus. A student had a most narrow escape. At Manchester on Wednesday the resident engineer for the Salford Sewage Works was walking along the banks of the Ship Canal when he was struck by lightning and killed. At West Bromwich, a stoker was struck by lightning and severely injured. Reports of great loss of life and property in France during the storm of Tuesday have been received. At Montauban, a woman was killed by lightning. At Perpignan a church belfry was struck and destroyed. A labourer, while working in the fields near Nantes, was struck dead, and at Charmes-la-Côte the lightning struck a tree under which six persons had sought shelter, killing three and severely injuring two others.

Actinism.—In a Paper recently read before the Franklin Institute, entitled "Is Actinism a Species of Electrolysis?" Prof. Edwin J. Houston remarked that it was now generally known that differences of potential existed in the various parts of a growing plant. Little was, however, known about these phenomena, probably because such differences of potential could be brought about by so many different causes that those arising from one set of causes masked those produced by another set. The more important causes which produced differences of potential in growing plants were (1) the chemical processes that occurred in growing plants; (2) molecular movements of liquids throughout the plant; (3) chemical action of the various liquid materials exuded at the surfaces of injured plant tissue; (4) the evaporation of moisture from the surfaces of the leaves; (5) the electrolytic decomposition of carbonic acid, or the various forms which carbonic acid derivatives assumed during assimilation. Another and an external source of differences of potential was to be found in the differences of electric potential that generally existed between the atmosphere that surrounded the plant and the soil in which it grew. The oxygen which resulted during the general process of deoxidation, under the influence of sunlight, appeared to be evolved mainly from the non-illumined face of the leaf, and the carbon, utilised by the plant for the production of its woody fibre, was mainly liberated at or near the illumined face. Assuming these facts to be as above mentioned, the decomposition in the leaf under the action of sunlight, of the carbonic acid, or its derivative compounds, probably partook of the nature of electrolytic decomposition. In this direction Prof. Houston suggests several lines of investigation. Perhaps a suitable leaf-battery could be devised by connecting in alternate succession the opposite faces of a series of leaves on a plant-stalk. A comparison might be made of the effects of sunlight and artificial light on such electrolytic decompositions. Supposing the presence of the differences of electric potential, due to the electrolytic decomposition, to be established, and the direction of the electric currents so produced known, it might be useful to ascertain whether an electric current led through the plant in the same direction as the current produced by actinism would not tend to increase the assimilation and the subsequent growth of the plant; and whether, on the contrary, an electric current sent in the opposite direction through the growing leaf would not tend to act as a check. In a series of experiments concerning the effects of the electric light on plant growth, made at the Experimental Station of Agriculture of the Cornell University in 1889-90-91, some important facts were discovered concerning electric plant-culture. These experiments seemed to show that electric light promoted plant assimilation, and sometimes hastened plant growth. It would seem, says Prof. Houston, to be a matter of considerable interest in the case of these experiments to ascertain definitely whether any marked differences exist between the action of the light produced by a steady current and that produced by an alternating current. In the line of investigations here suggested it would, of course, seem as if the electric decomposition would be less marked in the case of the light produced by an alternating current than that produced by a steady current. And that, therefore, in those cases where the electric light of the steady current had proved to be injurious to the growth and assimilation of the plants, that with the alternating current light such injurious effects should be less marked.

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(Concluded from page 682, Vol. XXVIII.)

§ 81. **The Silver Voltameter.**—In the preceding paragraphs we have given a full account of the method adopted by Lord Rayleigh and Mrs. H. Sidgwick* for the measurement of the strength of a current. In order to determine the electro-chemical equivalent of silver, the amount of silver deposited by a known current has to be determined. We shall now proceed to explain how Lord Rayleigh determined the quantity of silver with very great accuracy.

The deposits were formed upon metallic basins (usually of platinum) charged with a neutral solution of pure silver nitrate. The bowls were prepared by careful clearing with nitric acid and distilled water, with subsequent heating. After being allowed to cool in a desiccator they were weighed to $\frac{1}{10}$ milligramme on a delicate balance with trustworthy weights. "The anode,† by which the current enters the voltameter, is formed of fine silver sheet, suspended by platinum wire in a horizontal position near the top of the solution. In order to protect the kathode from disintegrated silver, which in our experience is invariably formed upon the anode, the latter is wrapped round with pure filter paper, secured at the back with a little sealing-wax. This arrangement appears to us for several reasons preferable to the vertical suspension of the electrodes in the form of flat plates. In the latter arrangement the deposited metal usually aggregates itself upon the edges and corners of the

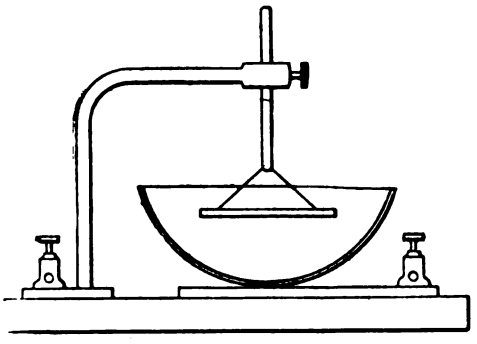

FIG. 56.—The platinum bowl rests by its own weight upon a copper plate connected with the binding screw on the right-hand side of the figure.

kathode with a tendency to looseness. Again, the solution rapidly loses its uniformity. At the kathode the solution becomes impoverished and at the anode it becomes concentrated. With vertical plates the strong solution soon collects itself at the bottom, and the weak solution at the top, so as to give rise to considerable variation of density. It is true that the horizontal position of the electrodes necessitates the use of a porous wrapping, which would increase the difficulty of determining the loss of weight at the anode. M. Mascart appears to have succeeded in determining this loss, but the disintegration which we have always met with rendered the attempt on our parts hopeless. It is possible that something may depend upon the mechanical condition of the metal, but as to this we cannot speak with confidence. The blackish powder left upon the anode has at first the appearance of being due to chemical impurity, but it occurs with anodes of the highest quality of silver and is completely soluble in nitric acid."

§ 82. **Effect of Silver Acetate.**—In the earlier part of his research Lord Rayleigh was much impressed with the importance of obtaining the deposit in a form sufficiently coherent to be proof against any risk of loss in the washing and subsequent manipulations. He found that the addition of a very small proportion of acetate of silver gave a much *better looking* deposit, which was less crystalline in appearance and of much closer texture than the deposit from pure silver nitrate. The apparent improvement led him to use solutions containing sensible amounts of acetate in nearly all the experiments carried out during the first year. Discrepancies, however, presented themselves of an amount much greater than had been expected, and they were of such a character as to show that the disturbing causes were to be sought in the behaviour of the voltameters, and not in the current-weighing apparatus. Thus it was found that the numbers obtained on the same occasion from the two voltameters in series, through which exactly the same quantity of electricity had passed, were liable to as great a disagreement as the numbers derived from experiments on different days. Lord Rayleigh made a laborious series of determinations with solutions containing more or less acetate, and for many months the results were fairly concordant, and were nearly taken as satisfactory. But on continuing the experiments with a fresh stock of solution (probably containing less acetate) a systematic change became apparent in the direction of smaller deposits. It had been thought that full precautions had been taken to secure adequate washing out of the silver salt from the deposit, and special experiments had proved that the weights were not appreciably changed by further washing with pure water, or by re-soaking in the depositing solution, with a second washing and drying like the first. A very careful attempt was made to test by analysis whether any of the silver nitrate was enclosed in the pores of the deposit; but the results of the analysis were felt not to be decisive, since the deficiency to be found in this way would correspond to only about one-third of the weight of salt actually present. The appearance of the deposits under the microscope was such as to suggest a doubt whether a complete elimination of the salt from the pores of the deposit was possible with any amount of washing. The diminution in the weight of the deposits in the later experiments, with a smaller amount of silver acetate present in the solution, might be attributed to a more complete washing out of the salt, rendered possible by the more open texture of the deposits. This encouraged Lord Rayleigh to test the behaviour of pure nitrate solutions.

"The result was a further small, but distinct, diminution in the weights, and we were now convinced that the use of acetate had been a great mistake, costing us six months' almost fruitless labour. When the deposits are taken upon the concave surface of a bowl they are coherent enough for convenient manipulation, without the aid of acetate. The danger of retention of salt or other impurity is far greater than of loss of metal, and this danger is aggravated by the acetate. Indeed, it would be scarcely too much to say that the danger is converted into a certainty, for from the fine pores of these deposits it seems almost impossible to remove the salt effectually."

§ 83. **Procedure with Silver Nitrate.**—In his later experiments, Lord Rayleigh used solutions containing only pure silver nitrate. He describes the solution usually employed as "a neutral 15 per cent. solution of pure silver nitrate." After the current had passed through the voltameter for from three-quarters of an hour to two hours, the platinum bowls were treated with hot and cold water and with alcohol. The bowls were passed backwards and forwards between cold and boiling distilled water. They were also soaked in alcohol, and then, while still wet with the liquid, plunged into boiling water. The object of this treatment was to produce as great a disturbance as possible within any pores that there might be in the deposited silver, and so to get rid of any silver nitrate which might be contained in them. The basins were then filled with

* "On the Electro-Chemical Equivalent of Silver," *Phil. Trans.* Roy. Soc., 1884.

† The terms *anode* and *cathode* are due to Faraday. Wishing to employ as names for the two surfaces, at which the current enters and leaves a decomposing body, terms which should distinguish one from the other, and at the same time should be free from all theory, he sought for a natural standard of electric direction, and found it in the earth. "If the magnetism of the earth be due to electric currents passing round it, the latter must be in a constant direction, which, according to the present usage of speech, would be from east to west, or, which will strengthen this help to the memory, that in which the sun appears to move. If in any case of electro-decomposition we consider the decomposing body as placed so that the current passing through it shall be in the same direction, and parallel to that supposed to exist in the earth, then the surfaces at which the electricity is passing into and out of the substance would have an invariable reference, and exhibit constantly the same relations of powers. Upon this notion we purpose calling that towards the east the *anode* (the way which the sun rises), and that towards the west the *cathode* (the way which the sun sets)."—*Exp. Res.*, § 663.

Digitized by Google

water and allowed to stand over night, so as to give free play to diffusion. They were then rinsed a few times, and placed in an air closet to be dried at 160°C. After cooling in a desiccator they were carefully weighed.

It was felt, however, that there might still be some of the silver nitrate remaining among the pores of the deposit. This would be decomposed on heating to a red heat, the NO_3 of the salt being driven off. If the bowl is now weighed again, the loss of weight will represent the NO_3. If W. grammes is this loss of weight, the silver which will be left behind on the decomposition of the $AgNO_3$ will weigh W. 108/62 grammes. Thus, to get the true weight of the electrolytic deposit W. 108/62 grammes must be substracted from the weight of the bowl after heating to redness. In attempting to carry out this process Lord Rayleigh met with several difficulties. It was impossible without injury to the bowls to raise them to a red heat, since silver and platinum begin to alloy at that temperature. To overcome this difficulty Lord Rayleigh attempted to use *silver* bowls, but found that their weights did not remain constant when strongly heated, the variation being much larger than could be tolerated when the highest accuracy was desired. On the other hand, the *platinum* basins might be heated to redness without changing more than $\frac{1}{10}$ milligramme. It was therefore decided to use the *platinum* bowls, but not to raise them to quite a red heat when containing the silver deposits.

"An exposure for five minutes to a heat just short of redness does not seriously damage the basins, and appears to be nearly, if not quite, sufficient to drive off the last traces of NO_3. With a pure nitrate depositing solution, and with the treatment for elimination of the salt above described, there was sometimes no loss on heating, but perhaps more often the balance indicated a loss of one or two-tenths of a milligramme. With respect to the interpretation of this, it is difficult to say whether or not it ought to be regarded as due to traces of salt retained in spite of all the washings. If so the true weight of deposit is smaller still by nearly twice (108/62) the apparent loss; but it is very possible that there may be traces of grease liable to be burnt off at a red heat, so that the loss in question cannot with confidence be attributed to nitrate." The weights adopted for the silver deposits were those found after heating nearly to redness for about five minutes.

§ 84. **Silver Chlorate.**—In some of the experiments Lord Rayleigh used deposits from chlorate of silver. The chlorate was used in a nearly saturated 10 per cent. solution, and also in a 5 per cent. solution. ("The tendency to crystallise upon the anode is an objection to the use of the strong solution, and probably makes itself the more felt in consequence of the paper wrapping, which impedes the free circulation of the liquid.") Voltameters charged with silver nitrate were included in the same circuit, so that the comparison was made under the most favourable condition. "The results show an exceedingly good agreement, and constitute perhaps the most accurate verification which Faraday's 'Law of Electrolysis' has as yet received." The weights of the deposits from chlorate and nitrate did not usually differ from one another by more than two or three parts in ten thousand.

§ 85. **Effect of Copper.**—In the earlier experiments Lord Rayleigh used anodes containing an appreciable quantity of copper. The copper evidently tended to accumulate in the solution, becoming after a time apparent by its colour even when neutral; on addition of ammonia a distinct blue was struck. Lord Rayleigh desired to ascertain whether under these circumstances there was danger of the deposits becoming contaminated. A distinctly blue solution was prepared, in which the proportion of copper to silver was considerable, and a deposit made. The texture was very much modified by the action of the copper, and the appearance was such that it was difficult to believe that the weight could be more than a small fraction of that of the simultaneous deposit from a pure silver solution. Some of the metal which adhered very loosely was lost in the washing, but the weights agreed to within a few milligrammes. When the deposit was dissolved in nitric acid and supersaturated with ammonia, the solution showed no trace of colour, although about one part of copper in ten thousand can be detected in this way.

§ 86. **Practical Details.**—Lord Rayleigh found that when the current through the voltameter was weak (not exceeding $\frac{1}{4}$ ampere) there was considerable latitude in the strength of the silver nitrate solution, and even a four per cent. solution was found to give satisfactory results. But for stronger currents it is advisable to keep the strength of the solution up to 15 or 30 per cent. If the solution is too weak in relation to the density of the current, the deposit has a tendency to looseness, and is liable to grow up in an irregular manner so as to meet the anode. In a 3in. bowl such a solution will allow of a current of about one ampere for a period of an hour. The strongest solution that Lord Rayleigh was able to use with a single voltameter was about two amperes, and for that purpose he employed a solution containing one part of salt to two parts of water. The deposit would probably have deteriorated if the current had been allowed to flow for much longer than a quarter of an hour, but in that time an ample amount of deposit (two grammes) was obtained.

"The practical conclusion is that currents not exceeding $1\frac{1}{2}$ amperes may be conveniently measured in a 3in. voltameter by using a strong solution and stopping the operation after about a quarter of an hour. A shorter time than this would hardly allow of sufficiently precise measurement when a high degree of accuracy is aimed at. For purposes where an error of $\frac{1}{3}$ per cent. is admissible, a duration of five minutes would be sufficient, and under these circumstances a stronger current would be unobjectionable."

"It will be seen that the application of this method to the measurement of such currents as are usually passed through incandescent lamps presents no difficulty, and we hope that it may be generally adopted as a control upon the indications of instruments depending for their trustworthiness upon the constancy of springs or of steel magnets. The anodes should be composed of fine silver sheet (about $\frac{1}{8}$in. thick), such as is sold for five shillings per ounce, and should not be allowed to approach the sides of the bowl too closely. As there need be no waste of metal, the expense of silver as compared with copper should not be allowed to stand in the way of its use. For practical purposes it will be unnecessary to take some of the precautions which we thought incumbent upon us. After rinsing a few times with distilled water the deposit may be left to soak for an hour or so, and then, after another rinsing, dried over a spirit lamp. After the lapse of another hour it may be weighed with a risk of error not exceeding a few tenths of a milligramme."

When stronger currents are to be measured the silver voltameter is less convenient. Platinum bowls of large size are not usually met with, but two or three may be combined *in parallel* without much trouble. In one of Lord Rayleigh's experiments the same current was passed successively through a single voltameter, and then through two arranged in parallel. The deposit on the single bowl thrown down in 13 minutes was 2·2327 grammes. Those in the other bowls were 1·0114 and 1·2215, altogether 2·2329, agreeing almost precisely. In this way, with three bowls, such as Lord Rayleigh used, there would be no difficulty in measuring currents up to five amperes.

§ 87. **Calculation of the Results.**—From the theory of the current weigher we have, as in § 78, the following relation between the current i and the difference of weighings observed in air m,

$$i = \mu \sqrt{m},$$

where for Lord Rayleigh's current-weigher $\mu = 0{\cdot}037048$. If w be the electro-chemical equivalent of silver in C.-G.-S. measure, viz., the quantity of silver in grammes deposited per second by the unit C.-G.-S. current, then the rate of deposit of silver by the current i is $w\,i$ or $w\,\mu\,\sqrt{m}$. In the table of results Lord Rayleigh gives a list of the values of the quantity $\sqrt{m}$/ (deposit per second) found in the separate experiments. The mean value of this quantity was 2414·45.

But

$$w = (\text{deposit per second}) \times \mu \sqrt{m}$$

so that

$$w = \frac{1}{2414{\cdot}45 \times 0{\cdot}037048} = 0{\cdot}0111794$$

Digitized by Google

In practical units the amount of silver in grammes deposited per ampere per hour is 4·0246. Lord Rayleigh quotes the two following results for the electro-chemical equivalent of silver :—

Kohlrausch, 0·011183.
Mascart, 0·011156.

§ 88. **Conclusion.**—I have now arrived at the end of my account of the careful and accurate research of Lord Rayleigh and Mrs. Sidgwick. In the earlier part of the series of articles I explained the principles on which the current-weigher works, and the methods employed in the calculation of its constants. In the last few paragraphs I have given an account of the treatment of the silver deposited, and in this part I have quoted many passages from Lord Rayleigh's memoir, since I felt that it would be very difficult to express the facts in language clearer and more concise than that employed by Lord Rayleigh.

It has been represented to me that the portions of the articles dealing with electrodynamics would be useful to students and others. I hope that these portions, together with some additions, may be republished in the shape of a book, so as to form a sort of sketch of electrodynamics. I should, therefore, be grateful for any corrections or suggestions which any of my readers might send to me at the Cavendish Laboratory, Cambridge.

I ought to add that Mr. Glazebrook has pointed out to me that some of the reasoning of § 38 is not quite sound. This I shall hope to correct in the book. I believe, however, that the arguments of the succeeding paragraphs are unaffected by this error.

AMPERE-CENTIMETRE, A MEASURE OF ELECTRO-MAGNETISM.*

BY CARL HERING.

It appears from the following deductions that an electric current multiplied by the length of the circuit will represent the number of magnetic lines of force generated by this current, or, in other words, that the number of lines of force generated by a current can be measured by the product of the current and the length of its circuit. A unit current passing through a unit length of circuit appears to generate a certain fixed and constant number of lines of force. This, of course, has reference to the electro-magnetism of the current itself, and does not include the influence of any magnetic bodies in the neighbourhood.

First of all it is necessary to show that amperes multiplied by length will give a unit of a similar nature to magnetic lines of force or flux, in order to show that an equivalent between the two may be given without transgressing the laws of physics. This may be shown conclusively by the aid of the dimension of these units in the absolute system. The dimension of current is $m^{\frac{1}{2}}\ l^{\frac{1}{2}}\ t^{-1}$, while that of magnetic flux (that is, number of lines of force, not their density per square centimetre usually represented by H or B, nor the intensity, as it is sometimes called), is $m^{\frac{1}{2}}\ l^{3-\frac{1}{2}}\ t^{-1}$. It will be seen that the former multiplied by a *length* gives the latter. This shows conclusively that ampere-centimetres, or ampere-feet and magnetic flux are units, of the same kind and can therefore be equated.

Having determined this point the following appears to show that every unit length of a circuit conveying one ampere generates a fixed and constant number of lines of force. Using absolute units, the intensity of magnetisation (or number of lines per square centimetre) at the centre of a circle of one turn, according to the well-known formula, is

$$H = \frac{2c\pi}{r}$$

in which r is the radius in centimetres and c is the current.

Now, the intensity of the field is different in different parts of the area enclosed by the circle, being greatest nearest to the wire, but it may be assumed that in all circles, large or small, the ratio of the intensity at the centre, to the average intensity in the whole circle, is a constant. Let this ratio be called K, then the total number of lines will be equal to the intensity at the centre multiplied by the area, and by K ; that is

$$M = \frac{2c\pi}{r} \times \pi r^2 \times K = 2c\pi^2 rK$$

* A Paper read at the Electrical Section of the Franklin Institute.

Dividing this by the circumference will give the number of lines per unit length of the circuit

$$2c\pi^2 rK \div 2\pi r = C\pi K$$

or per unit of current, this is equal to πK. It will be seen that this is a constant and is *independent of the radius r*. This means that the number of lines per unit length and per unit current is the same for all circles, and therefore also for a straight line, which is a circle of infinite radius.

From this it appears that, knowing this constant number of lines per ampere per centimetre or foot, the calculation of the total number of lines generated by any circuit or coil would merely be the product of the current, the length of the circuit, and a constant.

It should be remembered, however, that this deduction supposes theoretical conditions ; that is, in a filamentary wire having no appreciable diameter. How far the size of the wire introduces an error remains to be determined. At all events, if the diameter of the wire is small, is compared with the diameter of the coil, and specially if the coil, as it usually does in practice, contains iron which appears to concentrate the lines in it, and therefore probably attracts those circulating in the body of the wire itself, it may, doubtless, be assumed that the ratio of the flux in two coils would be equal to the ratio of their ampere feet, which proportion might be of use in dynamo construction.

The above deductions were made by the writer a number of years ago, but as they did not appear to agree with some existing laws at that time, the matter was laid aside. It seems, however, that subsequently some dynamo builders have advocated and used this system of calculation in preference to the other; and it was therefore thought best to publish this proof, hoping that some others, well informed on this subject, might point out the discrepancies, if any, and perhaps show the extent of the application in practice of calculating the magnetic flux of a current from the ampere-centimetres of the circuit.

[The following argument shows that Mr. Hering's contention is only true when certain conditions are fulfilled. Let A be the current in amperes flowing through a magnetising coil of n convolutions. Let B be the density of the lines of force in the core whose permeability is μ. Let the length of the magnetic circuit (supposed closed) be l. Then

$$\frac{4\pi n A}{10} = \frac{B}{\mu} l.$$

The total number of lines flowing through the iron core is N where

$$N = B \times \pi r^2,$$

r being the radius of the iron core. If L is the length of the magnetising coil, $L = n \times 2\pi r$.
From these equations we find

$$N = \frac{\pi r^2 \mu}{l} \cdot \frac{4\pi n A}{10} = L A \times \frac{2\pi r}{10 l} \mu,$$

so that N will only be proportional to L A (the number of amperes × by the length of the magnetising coil), provided

$$\frac{r}{l} \mu$$

is constant.

Mr. Hering's statement is, therefore, only true for closed magnetic circuits whose dimensions bear a constant proportion to one another, and the iron of which is magnetised to the same state of saturation, so as to have constant permeability. We allude further to this matter in our Notes column.—Ed. *E.*]

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-NIGHT) FRIDAY, June 3rd.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Metallic Carbonyls." By Ludwig Mond, F.R.S.

FRIDAY, June 10th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1.) "Some Points connected with the Electromotive Force of Secondary Batteries." By J. H. Gladstone and W. Hibbert. (2.) "Workshop Ballistic and other Shielded Galvanometers." By Prof. W. E. Ayrton and T. Mather.

ROYAL INSTITUTION.

9 p.m. Evening Discourse : "Magnetic Properties of Liquid Oxygen." By Prof. Dewar, F.R.S.

MONDAY, June 13th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co." All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

'THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates —The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Phillippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

THE TELEPHONE AND ELECTRIC TRACTION.

In the early months of 1889, when the Court of Appeal had given judgment in favour of the EDISON lamp patent and against the transformer patent of GAULARD and GIBBS, there were individuals sufficiently sanguine to prognosticate that the barren era of litigation was at an end, and that electrical engineers would ere long be far too busy building dynamos, laying mains, and advising town councils, to trouble their heads about "master" patents, however musty. And for a time everything pointed to the fulfilment of this pleasant prophecy. Applications for Electric Lighting Provisional Orders were as plentiful as blackberries; the Metropolis was divided into areas which looked extremely attractive on a properly coloured map, and the lucky allottees of these districts together with a few provincial concerns settled down to serious work. But all this was too Arcadian to last. Big as the "boom" was, it did not afford occupation for everyone. Mischief, if not work, we know is always found for idle hands to do, and to this fact, perhaps, as much as to any other, must be attributed the recent recrudescence of patent and other litigation. First one and then another ancient catalogue of claims has been unearthed; and at the present moment the central-station business alone, with the LANE FOX case only just on the list of Appeal Court II., is threatened by both the three-wire and the "feeder" men. The legal harvest, prospective and actual, is indeed a fine one; and to maintain it for some little time to come at its present high average the telephone companies, after having in a more or less subterranean manner persistently harassed the heavy electrical engineering industry, have now apparently made up their corporate minds to a policy which

Digitized by Google

may be summed up in three words, "Place aux téléphones." When we mention that at Bournemouth the supply of electricity is in no little danger of being summarily suspended owing to the action of the Western Counties and South Wales Telephone Company, that both the Thomson-Houston line at Leeds and the South Staffordshire Tramways are threatened with injunctions, and that it is sought to secure the insertion in the Blackpool Improvement Bill of the one-sided "Birkenhead" telephone protection clause, we think it will be generally agreed that the interference of the telephone companies with the development of the rest of the electrical industry "has increased, is increasing, and ought to be diminished."

American law is not English law; neither are the decisions of the Supreme Court of Ohio likely to carry much weight in Fleet-street; nevertheless, a brief glance at what has occurred across the Atlantic may provide potential litigants on this side both with arguments and encouragement. Writing under date May 11, 1889, our New York correspondent stated that there was considerable agitation on the part of the telephone companies in favour of compelling the electric railways to run complete metallic circuits. As agitation of this kind generally spells litigation, we have two months later the first legal decision on the question of whether traction or telephone companies were to double their wires. At the end of July it was decided at Chattanooga (Tennessee) that an injunction which had been obtained against the street railway of that cacophonous city should be dissolved, but that the railway people should be bound over to pay compensation in the event of their operations damaging the property of the telephone company. In contrast to this somewhat hesitating judgment we have about a year later the very emphatic and common-sense pronouncement of Chancellor Henry R. Gibson, in the action brought by the East Tennessee Telephone Company against the Knoxville Street Railroad Company. The telephone argument was that both companies could not use "earth" simultaneously, as the telephone current was "too delicate to contend with the railroad current," and that, as the telephone company had "a vested right to the exclusive use of the earth and the air as against every person using the same for electrical purposes," an injunction should issue. Chancellor Gibson, however, failed to see how the simple privilege of erecting poles along the kerb could be magnified into a grant of "the exclusive use of every inch of ground within the corporate limits for all the purposes of an earth circuit for electricity," and held that the Knoxville Street Railroad Company had the right to propel its cars by any system authorised by the municipality. Similar judgments were given at Albany, N.Y., and Lafayette, Ind.; and finally, on June 2, 1891, the Supreme Court of Ohio, in the action brought by the City and Suburban Telegraph Company against the Cincinnati Inclined Plane Railroad Company, held that the streets were primarily intended for the general traffic purposes of the public; and the fact of the motive power which facilitated that object being changed into something which interfered with a subordinate use of the highway ought not to make any difference. In Germany also, where the telephones are under the State, the Courts have held that the streets are properly used for locomotive purposes, and that nothing else using the streets incidentally should be allowed to interfere with locomotion.

In England we first heard of telephone opposition in connection with a proposed electric tramway at Weston-super-Mare. The next case which excited attention was that of the Wellingborough and District Tramroads Bill, the promoters of which, while forced to bear the expense of protecting the then existing lines of the South of England Telephone Company, were only rendered liable in regard to telephone circuits subsequently erected, if it could be shown that reasonable and proper precautions had been taken to insulate and protect them. But the most complete victory scored by the telephone interest was in July, 1890, in connection with the Birkenhead Electric Lighting Provisional Order Bill. A clause was inserted which obliged the undertakers to construct and work their entire system in such a manner as not to injuriously affect existing or *in futuro* telephone circuits. The wicked machinations of the telephonists have, it will thus be seen, been as uniformly successful in England as they have been the reverse in America. The reason is not far to seek. The National Telephone Company has spared neither pains nor expense in presenting its case; the electricity supply companies, badgered by Vestries, County Councils, and the Board of Trade, regarded one more clause-inserter with comparative indifference. Now that a municipal Bill has been interfered with and a supply company brought into court we may expect to see the tables turned.

The position of the telephone companies is indeed inherently weak. They undoubtedly render a great public service, but electric railways are destined to render a still greater. They certainly employ a most marvellous, ingenious, and delicate instrument, but that is no reason for connecting it to what has been termed an electrical cesspool. The advent of electric traction has not introduced a totally new condition of affairs; it merely threatens to convert an irritating nuisance into one that is intolerable. It is of no avail to urge that complete metallic telephone circuits are not to be thought of, because they already exist and are likely shortly to increase; moreover, the Treasury Minute, which we print in another column, runs as follows:—"It will be a condition of any licence to a new company that their system must be constructed entirely of twin wires on metallic circuits, so that there may be an assurance of its efficiency." To oblige electric railways to employ complete metallic circuits is to impose mechanical and other difficulties upon them approximating the impossible. On the other hand, no telephone now entering the field—apart altogether from electric traction considerations or Treasury edicts—would dream of running anything but complete metallic circuits. The mistakes of telephone pioneers in the past cannot be permitted to be a bar to electrical progress or an excuse for incomplete work to-day and improper construction in the future.

A NEW ERA FOR THE TELEPHONE.

No more important events have occurred in the history of the State Telegraphs during the past two-and-twenty years than those which were signalised by the Telegraphs Bill introduced into the House of Commons last week, and by the Treasury Minute, dated 23rd ultimo, and published in the newspapers last Monday morning. That the Post Office was seriously thinking of putting an end to telephonic competition with the telegraphs, so far as the trunk wire system is concerned, we had been led to expect by recent utterances of the Postmaster-General; but that a scheme of such magnitude and completeness had been prepared, and was ripe for promulgation, will be a surprise to most people, and an astonishment to many. We have now for the first time an official declaration—or what may be termed a confession—of what has been suspected for many years past, that the Telephone Companies were materially diminishing the revenue which normally belonged to the State Telegraphs; in other words, that the business which

Digitized by Google

the country bought and paid for was being rapidly diverted into private channels by the simple process of calling it by another name. The announcement will be useful if only to remind the country once again that the telephone is a telegraph, and that permission to work the younger system was merely provisional, and subject to its non-interference with the business of the older concern. To those who contended that the telephone, even as worked in this country, would serve as a feeder to the telegraph, and would, in fact, increase the earnings of the Post Office, this Treasury Minute is a decisive answer. In its earlier stage of growth it may be questioned whether the telephone did that; and certainly in its latest development it has done the reverse of that by diminishing the number of telegrams, just as has been the result of every conversation by telephone over the Government wires to Paris. The spread of the "trunk wire" system left no room to doubt the inevitable result; and as the extension of those lines could not in justice to the public interests be forbidden there remained no alternative but to acquire them and work them as part of the telegraph system proper.

It can hardly be said that the Government have got the best of the bargain. We are by no means convinced that the trunk wires can be worked for conversation purposes at a profit with the low tariff set forth in the Treasury Minute. Their acquisition may be regarded simply as an act of self-defence. If the wires prove unremunerative their extension will rest with the Post Office; and they can always be utilised telegraphically if not fully occupied telephonically. This is an advantage which no private telephone company could enjoy; and we think the inventors of the so-called "trunk wire" system of telephony may congratulate themselves on having forced the hands of the Government, and relieved their more legitimate business of a questionable and risky encumbrance. We have heard of freaks in the vegetable world which are technically described as the roots growing upwards and the leaves downwards. It was reserved for a modern telephone company to grow branches first and then to plant the trunks. The process is like constructing a railroad on the strength of a licence for a hackney carriage. The experiment could end only in one way.

As to the details of the new scheme under which the Post Office will take charge of all the main line wires, and permit connections to be made between their offices and the exchanges of the Telephone Companies, we must refer our readers to the Minute itself, which will be found in another column. On one or two points only can we find space to comment at present. It is expressly stated, and with very excellent reasons, that to the success of the scheme "united action on the part of the companies and the Post Office is necessary." There must indeed be friendly co-operation of a very ungrudging kind to assure for it any lasting success. Some of the conditions appear to put these friendly relations to a rather severe test. For example, the restriction as to written communications is removed, but the Post Office alone may deliver them. This is consistent with the rights of the Post Office; but it falls rather hard on the companies, and will prove expensive to the Government, who will have to bear the heaviest items of expense, namely for transcribing and delivering. Again, it is laid down that the whole trunk system shall be open to the public generally, and not to subscribers of the companies only. This, at all events, so far as post offices are concerned. On strict principles no exception can be taken to the enfranchisement of the general public; but it must operate to the disadvantage of the companies, and may lead to friction. On the other hand, the prospective admission of call offices in premises occupied by the Post Office will be a great boon to the companies; and the scale of commission for work passing between the telephone and telegraph systems appears to be on a fairly liberal footing. The charge for rental along railways, canals, &c., over which the Post Office have exclusive right, is reduced from 20s. to a nominal sum of 1s. per mile—a concession which does not count for much, however, now that the erection of trunk wires by the companies will cease. The royalties paid by the companies at present remain unchanged; but the Government in their Bill, an abstract of which will be found in another column, propose to assist in obtaining greater powers for the connection of exchanges by wires over private property. So far as the public are concerned the charges authorised by the Treasury ought to be well received. Our own misgivings are that they cannot be made remunerative, and that sooner or later the whole telephonic system will have to be reviewed, and finally transferred to the State; but that meanwhile the State will sustain a loss by partial acquisition, and the companies gain nothing by it. Should this prove to be the case the co-operation of both parties in the interests of the public, upon which so much stress is rightly laid in the Treasury Minute, though greatly to be desired, can hardly be expected.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

We regret that owing to the interference of the Council or the Institution of Electrical Engineers, or of a committee of that body, with our reporting arrangements, we are unable to present to our readers an abstract of the discussion which closed the last meeting of the Institution before the recess. As soon as we heard a rumour that the "Authorised Abstracts" were to be discontinued, we made, on April 8th, several suggestions through the Secretary, with the view of giving our readers an account of the discussions in the most useful form. Although ready to send our own reporter as formerly, we made, to avoid having the work done twice over, the proposition that we should contribute to the reporting expenses of the Institution at the usual rate per column, and receive in return an early type-written copy of the verbatim report, of which report we proposed to make a careful abstract, sending out proofs to the separate speakers. To these and other suggestions we received a courteous reply from the Secretary, dated April 11th, promising to submit the proposals to the Council at their next meeting, but intimating pretty clearly that there was not much chance of the Council acceding to them. Whether the Council, or their "editing committee," took six weeks to consider the question, forgot all about it, or thought we could wait, we do not know; but meanwhile the meetings continued, and, by way of getting something done, we inquired at the office of the Institution for the name and address of the official reporter, and arranged with him for a copy of the verbatim report. Our self-imposed task of abstracting, partially re-writing and condensing the discussion, sending out proofs to speakers, and marking those with an asterisk which were returned corrected, was no light one, but we ventured to think that it was worth doing. Only those who have taken part in these discussions are aware of the errors which must occur even in the most careful reporting of such highly technical matter, and of the importance of correction of the reports before publication, either by someone present at the meeting and versed in the subject, or by the speaker himself.

On May 25th we were at length informed that the Council hoped to be able to make arrangements for meeting our views, and a type-written copy of the reporter's notes of the last meeting was promised for Monday morning last. To this we immediately replied that we had been obliged to make our own arrangements, which were satisfactory, and which therefore we did not see any reason for disturbing. It appears that after our offer to contribute to reporting expenses and the full statement of our wishes, after obtaining the name of the reporter, in order to preserve the continuity of the reports

Digitized by Google

while the Council were making up their minds, they, without giving us any notice, intimation, or reason for their arbitrary action, ordered the reporter to desist from supplying us with copies of his notes. We only heard from him on Monday last, and on inquiry on Tuesday morning, found that the type-written copies mentioned had been exhausted, and that there was no other copy in existence.

We have set out these details in full, not to justify ourselves, but to give our readers some idea of the way in which the minor affairs of the Institution of Electrical Engineers are managed or rather mismanaged. There is probably no other scientific society in London or the rest of the country, the Council of which exhibits so much indecision and inconsistency in its procedure. There is surely none of twenty years' standing which either has not come to some definite decision about the publication of its proceedings, or could not do so in a fortnight. An editing committee has always been a feature of the Institution; the first volume was published in 1873 under the supervision of such a body. Whoever the members of this committee may be, we would rather serve our readers independently of them; for our endeavours to carry out the spirit as well as the letter of their edicts to the best of our ability, fail to satisfy that body. The publication of the discussions is appreciated, we believe, by our readers in all parts of the world, and it would be a pity if these debates were buried, as is done elsewhere, in the ponderous unread volumes of a Society's Journal. We hope that by next autumn some sensible measures may be adopted.

THE PATIN ALTERNATOR.

This high-pressure alternate-current machine recalls at first glance, says *l'Industrie Electrique*, the dynamo designed some ten years ago by M. Anatole Gérard; a machine which stopped at the projected stage, the need for large output alternators not being felt at that date. There are, however, in reality several points of difference. M. Patin's machine has rotating field-magnets and a fixed armature. It takes the place of a steam-engine fly-wheel, or it can be mounted direct on to the shaft of a turbine. This new arrangement has the double advantage of doing away with rope or belt transmission, which absorbs mechanical power and demands constant attention, and of reducing to a large extent the space occupied by machinery. Until now all direct coupled machines demanded angular velocities, which rendered necessary a recourse to high-speed steam engines, consuming a great deal of steam, and quickly wearing out. M. Patin's dynamo has been designed for coupling direct to Corliss engines or others of the same type, having a high efficiency and a small angular velocity.

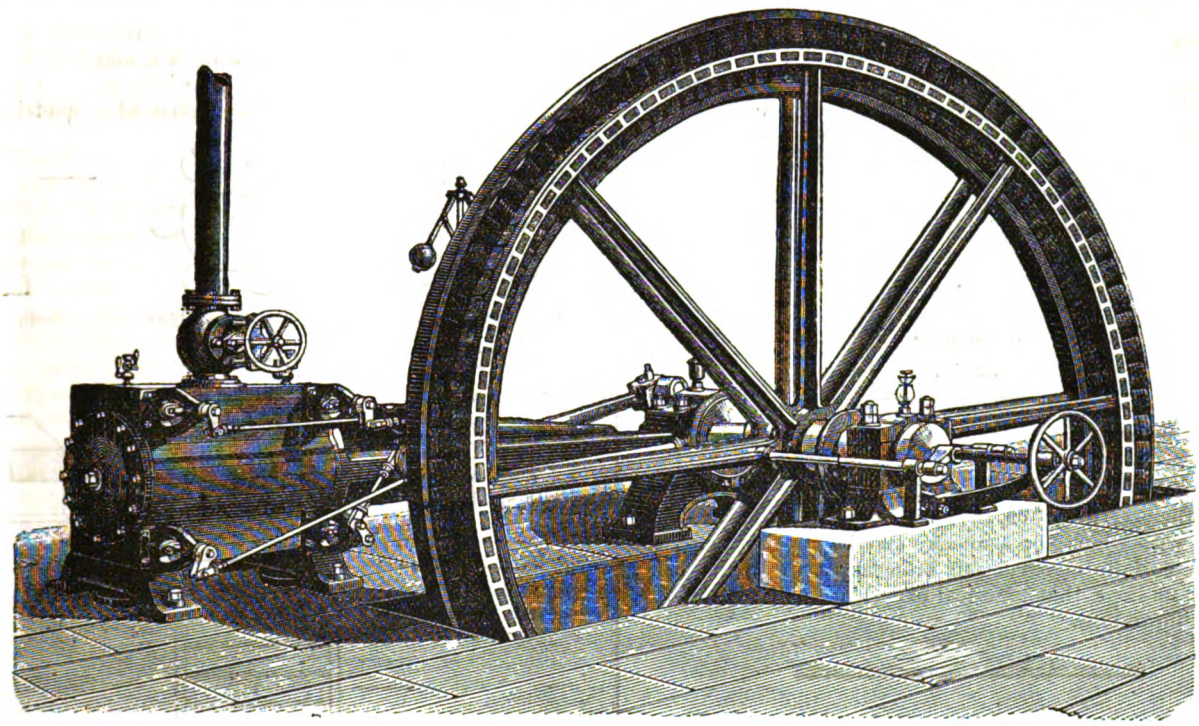

Fig. 1.—Patin 75-kilowatt Alternator.

The rotating field-magnet is mounted on the engine shaft and acts as its fly-wheel. It consists of two cast-iron rings (*see* Fig. 1) carrying soft iron pole-pieces recessed into it. The inner ring forms part of the fly-wheel itself, and the outer ring is joined to it by means of special arms as shown in Fig. 2. The fixed armature can be moved laterally for examining and quickly replacing coils in case of accident. The armature coils, which are composed of flat strips of copper and are wound on a frame of cast copper, have an arched shape, like the annular cylindrical space in which they are fixed. They are kept in position by bronze stirrups, bedded in the armature core with a special cement. (Fig. 2.) The displacement of the armature is effected by means of a screw actuated by a hand wheel placed near a bracket, and communicating its motion to two cross-pieces, which are solid with the armature core. Two insulated copper rings mounted on the dynamo spindle

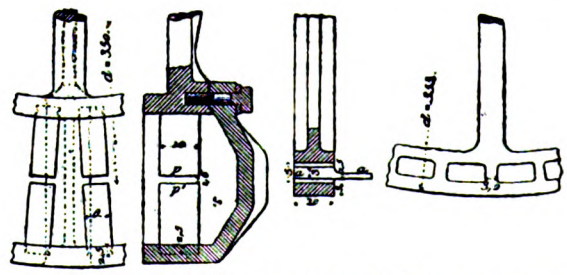

Fig. 2.—Details of rotating field-magnet and of fixed armature of Patin 40-kilowatt Alternator.

are connected up to the ends of the field-magnet coils; the exciting current from a special dynamo (sometimes distinct, sometimes arranged on a prolongation of the shaft) being brought to the rings through two rubbing contacts.

Digitized by Google

Figs. 2 and 3 relate to a 40-kilowatt machine. Fig. 1 is a perspective view of a 75-kilowatt alternator, of which the following are the principal data :—

Number of field-magnet poles	76.
Electromotive force	2,400 volts.
Current	31 amperes.
*Peripheral speed	14·66 metres per second.
Armature resistance	0·75 ohm.
Length of wire on armature	520 metres.
Section	3 sq. mm.
Excitation losses	2,500 watts.
Armature losses	730 watts.
Electrical efficiency	96 per cent.

* 2,886ft. per minute.

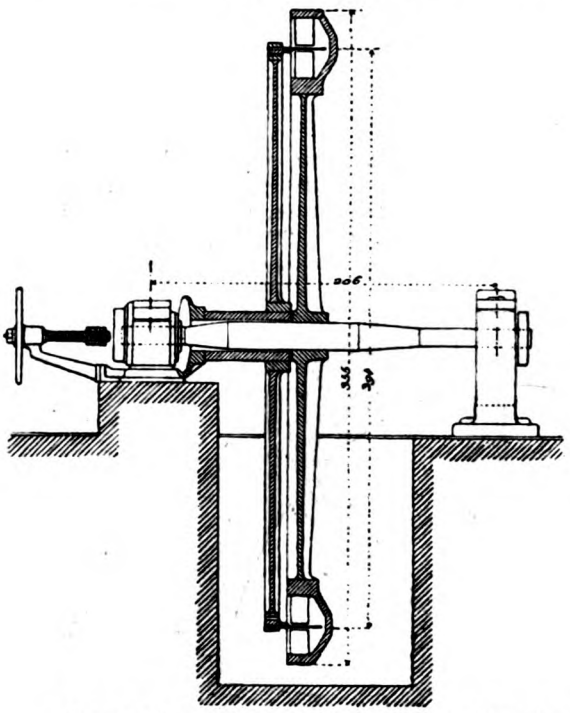

Fig. 3.—Cross-section of Patin 40-kilowatt Alternator.

The arrangements adopted by M. Patin in his new alternator commend themselves to us, says *l'Industrie Électrique*, owing to the ease with which the armature can be repaired, and the simplification of its construction brought about by its being fixed. Let us hope that practical experience will confirm this favourable impression.

A PORTABLE INSTRUMENT FOR MEASURING THE STRENGTH OF MAGNETIC FIELDS, WITH SOME REMARKS ON THE STRAY FIELDS OF DYNAMOS.

BY EDWIN EDSER AND HERBERT STANSFIELD.

The instrument which was briefly described in our report of the recent meeting of the Physical Society was designed to give direct readings for the strength of magnetic fields, in order to obviate the difficulties, sometimes practically insuperable, attending the ballistic method. Portability, a fair degree of accuracy, and a wide range were the qualities sought. The instrument as now constructed has an error of only about two per cent., is both small and light, and can be used to measure any fields from two or three lines per sq. cm. upwards. The only accessories required are a resistance box and a dry cell, or other source of a constant E.M.F.

The principle of the instrument is the inversion of that of the d'Arsonval galvanometer ;* the torque necessary to restore a small coil through which a current circulates to its initial position parallel to the lines of force, being a measure of the strength of the field at the position of the coil.

* The same principle has been used by Messrs. Siemens and Halske in some investigations on the rotary current motor. See *Electrical Review*, June 15, 1891.

A section of the instrument is shown in Fig. 1. A B is a small coil, wound of 44 B.W.G. wire, to 50 ohms resistance, half is attached to each side of a small sheet of mica, C D, to which a small pointer C is attached, which moves over a scale, to

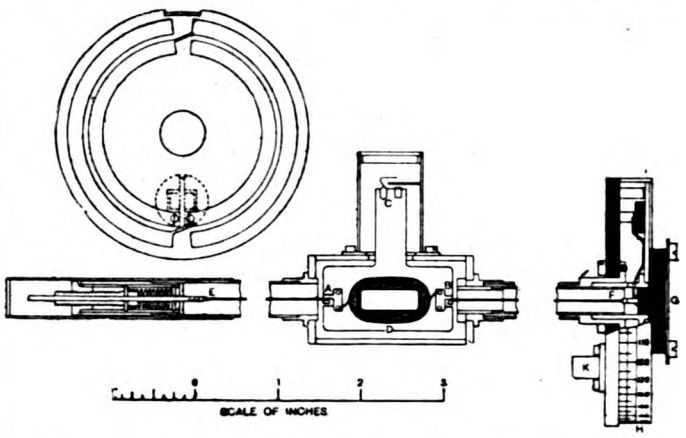

Fig. 1.—Sectional view of Edser and Stansfield's instrument for measuring magnetic fields ; with enlarged view of circular commutator.

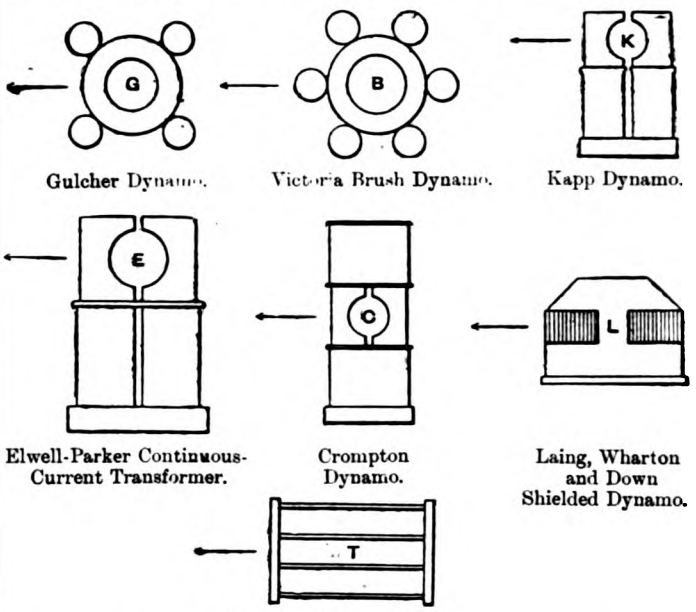
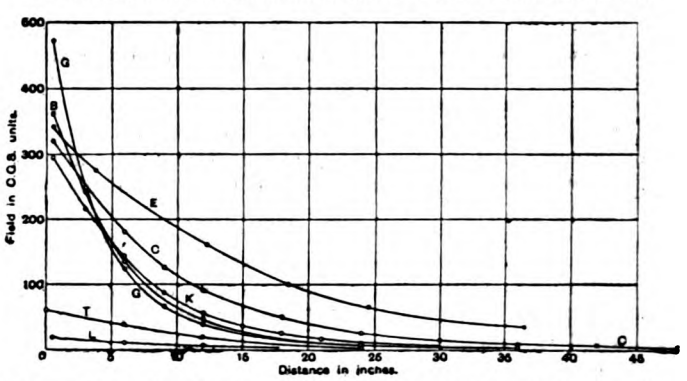
indicate the position of the coil. The suspension consists of two fine strips of German silver wire, A E and B F, which also serve to carry the current to and from the coil. A E is connected at E (by means of a special form of geometrical slide,



The arrows show the direction in which the various measurements were made.



Curve showing decrease in strength of stray magnetic fields at various distances from the dynamo.

Fig. 2.

designed to combine a spring suspension and an adjustment for torsion), with the case of the instrument ; B F is insulated at F from the case by a block of ebonite F G, clamped to a

Digitized by Google

graduated torsion head H I. The coil is approximately balanced, but in order to eliminate any errors due to want of balance, a commutator is enclosed within the torsion head, by means of which readings can be taken on either side of the zero. This commutator is so constructed that on turning the torsion head the current is sent in one direction through the coil, this direction being reversed on reversing the direction of the torsion. K is a plug contact for connecting to the battery used.

For a source of current a Hellesen dry cell has been used, the E.M.F. on a circuit of 50 ohms being practically constant over a longer period of time than that required for an experiment.

To vary the sensitiveness of the instrument, a resistance box is connected up in series with the battery and instrument. Thus, the resistance due to the instrument being 50 ohms,* if F be the field corresponding to any given degree of torsion with no external resistance, the field corresponding to the same torsion, with $n \times 50$ ohms external resistance, will be $(n+1)$ F.

The constant of the instrument was determined by finding the torque necessary to restore the coil to its initial position parallel to the lines of force, in the uniform field between the coils of a Gaugain pattern galvanometer, through which a known current circulated. In using the instrument, the direction of the field at any point is first determined by means of a small pilot needle; the instrument, joined up through the resistance box with the cell, is then placed so that the axis of the coil and the axis of suspension are at right angles to the lines of force, and the torsion head is turned till the small pointer C is brought to the zero of the scale over which it moves. The reading of the torsion head being taken, the operation is repeated on the other side of the zero.

If θ = mean of these two readings.
n = multiple of 50 ohms external resistance.
C = constant of instrument.
Field = $C(n+1)\theta$.

By permission of the Committee of Experts, and of the various firms exhibiting, a number of measurements have been made at the Crystal Palace Electrical Exhibition, some of the results of which are embodied in Fig. 2. These curves show the strength of field at various distances from the different types of dynamos. It is noticeable that in the multipolar machines (B and G, Fig. 2) the strength of stray field falls off much more rapidly than in the bipolar types.

Mr. Harrison having kindly lent a watch with a brass balance-wheel for testing purposes, it was determined that a field of 10 C.-G.-S. units did not materially affect its rate, but that a field of 40 C.-G.-S. lines entirely upset its working. This would tend to show that at 3ft. from a dynamo injurious effects may be apprehended.

ON THE CAUSE OF THE CHANGES OF ELECTROMOTIVE FORCE IN SECONDARY BATTERIES.

The following is an abstract of the Discussion on the above Paper, which was read before the Institution of Electrical Engineers, on May 12th and 19th, by Messrs. Gladstone and Hibbert:—

* Abstract revised by speakers.

THURSDAY, MAY 19TH.

*Mr. G. H. ROBERTSON, speaking in Prof. Armstrong's name as well as in his own, said that Messrs. Gladstone and Hibbert's Paper was undoubtedly an important contribution to the discussion of a very complex and difficult problem; but the verdict on it, he thought, must be one of "non-proven," as indeed Prof. Armstrong and himself were ready to admit was the case as regarded their own recent attempt to display the inner working of the lead-sulphuric-acid lead peroxide cell. While accepting the results, he must decline at present to accept the author's interpretation of them; indeed, he thought, Prof. Armstrong and himself were justified in claiming them in support of the explanation they had advanced in their Royal Society Papers, which it seemed the authors in a measure sought to traverse. Divested of all details, the contention of Messrs. Gladstone and Hibbert appeared to be, that practically action was limited to the occurrence of the series of interchanges pictured by the equation—

$$Pb \,\Big|\, \underset{aq}{SO_4H_2} \,\Big|\, \underset{aq}{\overset{}{\overset{}{\overset{

ceivable that such a counter-electromotive force might exist; moreover, there was the possible influence of the lead support to be considered. Further consideration of the matter has since led them more and more to favour the view that a considerable counter electromotive force was operative throughout discharge, which was conditioned by the "peroxide" in solution at the lead peroxide plate. Its presence could not be denied; and if present it would seem that it must be operative. The explanation that they should give of the variations observed by the authors would be obvious from these remarks.

*Mr. CROMPTON thought the Paper a valuable contribution to the science of the subject Some six years ago Mr. Howell and himself had taken out a patent to introduce artificial means for circulation, in order to equalise the strength of the acid throughout the cell. They had utilised the increase in the resistance of H_2SO_4 when its density varied above or below that of a 30 per cent. solution to make the electrolyte self-regulating as regards its density. Any increase or decrease of specific gravity having the same effect of increasing the resistance of the electrolyte, a little thought would show that this property was of the highest importance, as any change in specific gravity would have the tendency of producing the compensating effect of decreasing or increasing the action at that particular point. Although his coadjutors and himself hailed the results obtained by such workers as Dr. Gladstone, Prof. Ayrton, Mr. Robertson, and others as of the greatest interest, yet they looked on the results with a certain amount of suspicion. The actions in an accumulator were so very complicated and so very difficult to follow, that he would hesitate to accept Dr. Gladstone's theories as proved until they had stood the test of a much longer series of experiments, and under wider conditions than those detailed in the Paper. Many results which he (Mr. Crompton) had appeared to arrive at after experiments on small cells had been absolutely contradicted by subsequent experiments with bigger plates and larger cells. For that reason he was one of those who believed that no quantitative experiments were of the least value until they had extended over some years. Mr. Howell, Mr. Clauss, and himself had been for six or seven years on the job. They could not introduce any means of artificial agitation, and it therefore became necessary to so proportion the spaces between the plates that the greatest freedom to circulation was given. After very long quantitative experiments they had arrived at the conclusion that the space occupied by the electrolyte between the plates must be nearly twice that occupied by the plates themselves. Again, the weaker the plates were mechanically up to a certain point, the stronger they were chemically. After many years they had fixed on a size of crystal which had given good results. His spongy lead was very spongy on the negative side, and it was of great importance to know at what strength of electrolyte the delicate crystals would be attacked by the electrolyte itself. At ordinary temperatures, that was under 75° F., he found that the critical density was 1,250 or 1,260. He wondered if Dr. Gladstone would be able to account for the very curious fact that in all the cells he (Mr. Crompton) had experimented with there was always a slight rise of electromotive force after the first rapid fall shortly after the commencement of discharge. He wished to call attention to a foreign contribution to the subject which ought to be read. That was a Paper contributed to the *Elektrotechnische Zeitschrift* of January 8th by Dr. Krügel, in which he pointed out the cause of that bugbear of all accumulator users, the self-discharge of negative plates under certain conditions. Dr. Krügel attributed it entirely to metallic impurities originally present in the electrolyte. Up to a very late period of the discharge the greater proportion of those impurities still remained on the lead plate, and it was only at a particular moment, almost the moment of reversal, that they got them in solution and were able to detect them.

*Mr. E. W. SMITH said that the first point he wished to call attention to was that in the Edinburgh Paper attention was called to the fact that after rest the potential difference rose when a discharge commenced. Another point was the decay of the positive grid. He did not think it was due to the formation of the sub-sulphate Dr. Gladstone mentioned. The cause of it was to be sought in the negative plate. If, as Dr. Gladstone pointed out, there was a considerable amount of local action on the positive grid at the end of charge during rest, should there not be a great deal more during the charge itself, when the sulphuric acid was of great density there? The author's hypothesis as to the substance which might be formed on acid strength next the plates becoming very low was not borne out by the facts. Dr. Gladstone mentioned the fact that on trying to calculate the electromotive force from thermo-chemical data he did not get results which agreed with his experiments. Now, the Edinburgh Paper showed, and Prof. Duncan also showed, that there was a distinct cooling of the cell during discharge, as if the energy required to separate the sulphuric acid from the solution was derived from outside as heat. If that was so, Dr. Gladstone should find by experiment an electromotive force somewhat higher than by calculation.

*Mr. J. SWINBURNE: Referring to Dr. Gladstone's theory that the variations of electromotive force were due to the liberated acid in the coatings, he would like to say as a matter of personal justice to himself that this was pointed out by him in 1883 in a little book on electrical units. Lord Kelvin's law that the electromotive force ought to be got directly from thermo-chemical data was wrong. It was pointed out by Helmholtz in 1882 that there was a second term, the temperature coefficient to be considered. In the particular case taken by Lord Kelvin (the Daniell cell) there was no temperature coefficient. It was pointed out by him theoretically that a secondary battery ought to cool on discharge. Mr. Crompton referred to the curious rise on discharge. He believed the phenomenon was due to the resistance of the cell falling, and not to the electromotive force increasing. He did not want to go into personal matters too much, but the question of self-discharge was brought before the Society by him in 1886, when he pointed out that the least impurities in the acid, anything that could settle on lead, would settle on lead, and would give rise to local action.

*Mr. W. HIBBERT pointed out that in the Paper the section which dealt with the thermo-chemical values was avowedly and professedly abbreviated; but the calculated values agreed with the observed ones very well. At the top of the curve—that was to say, when the plates were in pure H_2SO_4—the calculated value was something like 2·62 volts, whilst the observed was 2·607. At intermediate points the observed values should be, roughly speaking, something like one-tenth of a volt higher than the calculated ones. Detailed consideration of the question was reserved for future consideration. With reference to the remarks read by Mr. Robertson, a good many suggestions and fancies were mentioned in that Paper; but unfortunately experiment was directly against them. Dr. Gladstone and himself tried the effect of adding hydrogen dioxide to the cell, and found no effect worth noting—nothing that could be dwelt upon. The change of electromotive force on adding a fair amount of hydrogen dioxide was almost negligible. They also tried adding persulphate of potassium, with a like insignificant effect, so that their results could not be due to those substances. The form of the curve in Fig. 3 as one carried it down from strong to a very weak acid was not unlike the discharge curve observed in the Paper by Prof. Ayrton and his colleagues, and fully explained why there should be a critical point at about 1·8 volts. Mr. Crompton, in speaking of these experiments having been made with small cells, suggested that, therefore, they might be liable to suspicion. But the Paper was exclusively dealing with electromotive force, and in no case did electromotive force pure and simple depend on the size of the cell. Mr. Swinburne mentioned Kelvin's law as being incomplete. That was true. But Preece showed in 1883 that the temperature coefficient—which was the second term of Helmholtz—of an accumulator was exceedingly small. Such a term would, therefore, be practically negligible.

Mr. HIBBERT, in answer to a question put by the President, said that with the exception of one professed discharge curve at the end of the Paper, the experiments involved no question of current, but were pure electromotive observations made by potentiometer or condenser.

The PRESIDENT remarked that, in connection with what Mr. Crompton and Mr. Swinburne had said, it was exceedingly important to distinguish between the electromotive force of the cell and potential difference at the terminals.

*Dr. GLADSTONE, in replying to the remarks of the various speakers, said he was very glad indeed to hear that his theory had been so distinctly recognised by several experimenters before. As to the chemical changes that take place, he did not think there could be much doubt as to the formula he had put on the board in regard to the ultimate results in both directions. There might be a great deal of difference as to whether there were any intermediate reactions taking place. It was quite possible that that which Mr. Robertson put on the board in his formula might exist. These were matters of speculation, and it was one of the most difficult things in the world to tell what any intermediate stage in the chemical reaction was. They knew where they began, they knew where they ended, but of the intermediate stages they knew nothing. They could not say at present exactly whether it was the absolute sulphuric acid that was acting in these batteries, or whether it was a hydrate. The matter was not determined by means of the thermo-electric calculations. As to the presence of the liquid peroxides, and as to the difference of opinion and difference of results of experiments between Prof. Armstrong and Mr. Robertson and themselves, he was rather at a disadvantage, because Mr. Robertson knew all about the experiments of Mr. Hibbert and himself, while he did not know the experiments which Mr. Robertson had performed. At present they only knew some of the results, and they could not repeat the experiments because they did not know how to do so exactly in the form adopted. He hoped that, as in many of these kinds of investigation, it would be found that there was a certain amount of truth on both sides. He had no doubt whatever the peroxides did make some kind of change of the electromotive force; but all he could say was that they could not find any definite amount of it. As for the statements in the Paper, he thought that such coincident results from a number of different directions, together with the number of different arguments which had been brought to bear, pointed to one conclusion, that we must attach a very large amount of importance to the strength of sulphuric acid against the working surfaces of the plates when we consider the variation of the electromotive force.

LONDON CHAMBER OF COMMERCE.

ANNUAL MEETING OF THE ELECTRICAL TRADE SECTION.

The annual meeting of the Electrical Trade Section of the London Chamber of Commerce was held last Friday, at the offices of the Chamber, Botolph House, Eastcheap; Mr. R. E. B. Crompton presided.

The CHAIRMAN said that his first duty was to inform them that his period of office had come to an end; and he wished briefly to state the work which had been done during the last two years, and what still remained to be done. Speaking generally, he might, he thought, say that, on the whole, they had reason to congratulate themselves on the success of the formation of their Section. He thought it had, to a certain extent, promoted what it had been intended to promote—free intercourse between the members of their profession. They had met very frequently there, and had discussed matters in the general interest, and that had been the cause of their meeting elsewhere. Those who had previously considered themselves trade

Digitized by Google

rivals, and hardly on speaking terms, were now upon closer terms, and had been able to work together in carrying out matters of common interest. He did not propose to take up their time by running through the list of matters, small or great, which had been undertaken in the last two years. On one occasion the Section had been in a position of antagonism towards the Board of Trade. The question arose out of the decision not to permit any longer the use of overhead wires. This decision appeared manifestly unjust after the Board had issued a very clearly laid down code of regulations on the subject of overhead wires, on the strength of which a great deal of capital had been spent. He was not one of those who upheld the use of overhead wires in crowded cities, but there was no doubt that they had their uses in country places. At any rate, he thought the decision of the Board of Trade, that, under no circumstances, would they allow the use of overhead wires, was to be combated with all their strength. As a consequence, they practically canvassed the whole profession, and, through the instrumentality of Mr. Murray and his staff, they were able to put such a powerfully signed petition before the Board of Trade that the latter practically at once reconsidered their decision. He did not think that in future the trade would be treated in such a brusque manner. One or two very important matters were started last year, but were not carried forward—principally, he thought, on account of the very happy state of their trade—that was to say, most of them had been so busily employed that they not been able to give any time to abstract questions. He might allude to the standardising of the machinery they used, so as to make it interchangeable as far as possible. The standardising of screws had now been carried out, and he thought that 98 per cent. of the manufacturers of electrical appliances were using the one form of screw which was proposed a few years ago by the Small Screws Committee of the British Association. This was now, therefore, practically universal in England: and as it was interchangeable with the Swiss screw trade, it might be said to be practically universal. By means of Mr. Murray's staff they had been able to do two other things. They were able to arrange that those who wished to visit the Frankfort Exhibition last year could do so in a body; and he thought they had derived some small advantages from this. They were received very well at Frankfort, and treated most hospitably by the Committee of the Exhibition. Another point on which they took collective action was in inducing the Directors of the Crystal Palace to postpone their Exhibition. No doubt, it would not have been half as good had it not been delayed. The display only reached its full from about the middle of February, or four months later than the date originally proposed by the Crystal Palace executive. He thought that this showed that they were right in the decision they took to endeavour to obtain a postponement. The burning matters still before them were the question of the telephone service, and how far the interests of the telephone companies and those of the heavier electrical industries could be brought together so as not to clash. In some respects it appeared as if these interests did clash; but it would be a great pity if a large amount of money were spent upon law if the questions could be settled by friendly meetings between the representatives of the different interests. A great deal had been done on the continent of Europe in this respect, and he thought he might suggest to those who followed him that if they could have before them the idea of some such Congress to settle these matters as was carried on at Frankfort last year, it might save the time, temper, and money of all concerned. He must render tribute to the extreme courtesy which had been shown to him and those who with him represented the heavier side of electrical engineering by the representatives of the telephone companies, particularly Colonel Raynsford Jackson.

Colonel Raynsford Jackson said that the next subject before the meeting was the appointment of a Chairman and two Deputy Chairmen of the section. They had observed the manner in which Mr. Crompton had presided over the Section, the skill with which he had brought the various subjects which the Section had had to deal with before it, and the devotion he had always manifested in the interests of the Section. He was sure that they would agree with him that the right thing for them to do was to ask Mr. Crompton to place his services at the disposal of the Section for another year. He therefore proposed the re-election of Mr. Crompton as Chairman of the Section.

Mr. R. J. Jenkins also testified to the admirable way in which Mr. Crompton had discharged his duties, and seconded his re-election.

Mr. Crompton said he fully appreciated their great kindness, but his decision was irrevocable.

Mr. Emile Garcke said they had already used great efforts to induce Mr. Crompton to withdraw his resignation, but they had not been able to do so. He was only echoing the sentiment of the whole Section when he said that they received Mr. Crompton's resignation with very great and sincere regret. At the same time, it must be remembered that Mr. Crompton had served for four years, and it was only right for the Chairman and the two Vice-Chairmen to tender their resignations on that occasion, so as to afford the Section the opportunity of appointing their successors. The period for which they had held office had been longer than the custom of the Chamber permitted, and the position had been a very serious addition to Mr. Crompton's numerous engagements. While he was on his feet he might be allowed to put himself in order by proposing a resolution for appointing a successor to Mr. Crompton, and he suggested to them the name of Major Flood Page, who had been Vice-Chairman of the Section since its formation, and who had devoted very considerable attention to its affairs. Major Flood Page had had opportunities of being in touch with everyone connected with the industry, and this was a great advantage in connection with the position of Chairman. He was also intimately acquainted with all the questions that came before them, and he (the speaker) felt sure that he was only serving the interests of the industry at large by proposing the appointment of Major Flood Page as Chairman of their Section. He might also refer to a suggestion which had been made to them by the Chamber namely, that the Chairman and Vice-Chairmen of the Section should be appointed for a fixed term. If they were of that opinion he would frame his motion so that Major Flood Page should be asked to accept the position of Chairman for the ensuing two years.

Colonel Raynsford Jackson seconded the motion, which was unanimously adopted.

Mr. R. S. Erskine then proposed and Mr. Henry Edmunds seconded the election of Mr. Garcke as Deputy Chairman, and the motion was unanimously agreed to.

Major Flood Page after having expressed regret at Mr. Crompton's retirement observed that it was very important for all interests to be represented; and he therefore proposed the appointment as second Deputy-Chairman of Colonel Raynsford Jackson, who represented the great telephone interest.

Mr. Jenkins seconded the motion.

Colonel Raynsford Jackson, while thanking Major Flood Page for proposing him, said he felt obliged to decline the honour.

On the motion of Mr. A. R. Bennett, Mr. Alex. Siemens was appointed a Deputy-Chairman.

At this point Mr. Crompton vacated the chair, which was then occupied by Major Flood Page.

The newly-elected Chairman, after thanking the meeting for the honour conferred upon him, said he could not for one moment pretend to occupy the same position in the electrical world as that which was held by Mr. Crompton. Mr. Crompton was thoroughly versed in the whole of the scientific and engineering aspects of the question, as well as its commercial aspect, whereas he himself represented only the commercial aspect of the industry. No one, however, could ever deprive him of the honour of having introduced the electric light into the colonies of New South Wales, Queensland, and New Zealand. He could not add Victoria, as the agent of the Company of which he was then general manager had already put up a few—he believed five—incandescent lights a day or two before he (the speaker) arrived at Melbourne. He had ever since taken an active part in the commercial side of electricity. He would endeavour to do his best to promote the interests of the Section, and he knew that he would have the advantage of Mr. Crompton's experience and that of the Section at his disposal. The next business they had to deal with was "to consider the desirability or otherwise of the Section following the precedent of other Sections of the Chamber, in convening the whole of the membership of the Section to all future meetings, appointing special committees to deal with special subjects." He thought there would be hardly two opinions on this matter. At present they had a large Section and a Committee, the latter consisting of about 35 out of 200. Any member of the Section was entitled to attend any special meetings, but could not vote. It would put a certain amount of expense on the Chamber, but if approved in future all members would be convened, and Special Committees would be appointed, and would report to the Section.

On the motion of Mr. Siemens, seconded by Mr. W. W. Beaumont, it was resolved that the Section should follow the precedent of the Chamber in regard to the matter in question.

The Chairman said that they had next to consider the attitude of the electrical trade towards the Chicago Exhibition.

Mr. Kenric Murray stated that the English Royal Commission which had been organised to promote the interests of British exhibitors at the Chicago Exhibition had requested the London Chamber of Commerce to act as the London Committee, and the Chamber had accepted this duty. Under ordinary circumstances they would probably have requested the Electrical Section to consider whether it would take any steps to be represented at Chicago, but he understood that Mr. Preece had been occupying himself specially with this question; and perhaps, therefore, it might not be desirable for them in any way to appear to be interfering with the action of that gentleman. Otherwise, if it were desired by the Section to organise an exhibit apart from individual exhibitors, this could be proposed.

Mr. Alex. Siemens suggested that this was the case where a Special Committee would be very important, and he proposed

Digitized by Google

"That a Special Committee be appointed to report to the Section, after conferring with Mr. Preece and others, as to the attitude they recommend the Electrical Section to take with regard to the Chicago Exhibition, and that the Committee consist of Messrs. Albright, Ravenshaw, Binswanger, and Wharton."

Mr. GARCKE seconded the motion, which was carried unanimously, after the addition of the names of the Chairman and the Deputy-Chairmen to the Committee.

The CHAIRMAN stated that the next subject on the agenda paper was the telephone question. Mr. Murray informed him that nothing further had been done since the deputation of the Chamber—which had taken up the question generally—saw the Postmaster-General.

Colonel RAYNSFORD JACKSON stated that they were all aware that there was an Association for the Protection of Telephone Subscribers, and that it professed to be affiliated with the Chamber of Commerce. A circular, however, had been issued by the Association which, he thought, showed that it could not properly be affiliated with the Chamber. The Association had entered into arrangements with the New Telephone Company, had converted itself into a body of canvassers for subscribers for that Company, and had secured for the members of the Association special privileges. It had been expressly stipulated that no others should have the special privileges allowed—indeed, agreed to be given—to the members of the Association. He thought it was quite impossible for an impartial body like a Chamber of Commerce to have affiliated with it an Association which was neither more nor less than a canvassing body seeking advantage for its members at the expense of others—canvassing also to assist one Telephone Company in opposition to another, both being members of the Chamber. Having read two of the conditions—Nos. 4 and 7—which the Association said it had made with the New Telephone Company, the speaker observed that it was unnecessary for him to add anything further.

The CHAIRMAN stated that he had been informed by Mr. Murray that although the Association had in fact been affiliated to the Chamber the Council of the Chamber had complained to the Association of the use which it had made of the name of the Chamber, and the Association had promised to withdraw all such use in their future circulars.

Colonel JACKSON said he did not think that this met the necessities of the case. Here was an Association which had a specific object—to take care of the members of the Association, and, as the reward of certain privileges given to it, to canvass for subscribers for the New Telephone Company. He maintained that the work which the Association had to do did not entitle it to have the countenance, assistance, and support derived from affiliation with an impartial, independent, fair-minded Chamber of Commerce.

Mr. JENKINS said he was strongly of Colonel Jackson's opinion; and he was sure that the Council would, on consideration, see that it was detrimental to their interests for there to be any attempt to take up one scheme as against another.

The CHAIRMAN suggested that Colonel Jackson should put his remarks in the form of a resolution to be submitted to the Section with a view, if carried, to its going before the Council. It was manifest that the matter was one which must be dealt with by the Council, and not by the Section.

Mr. SYDNEY MORSE thought that the Association should have received notice of the discussion.

The CHAIRMAN stated that no Association of the kind mentioned was a member of the Section *quâ* Association; but some individual members of the Association were present as members of the Section. In giving notice of these meetings only individual members of the Section were communicated with.

Mr. A. R. BENNETT stated that he was not a member of the Association referred to, but he knew something of the matter. Colonel Jackson had said that the object of the Association was to canvass for subscribers to the New Telephone Company. That was a mistake. The object of the Association originally was to investigate complaints which had been urged by subscribers against the existing telephone service. The course which the Association had taken in supporting the New Company was the outcome of that investigation. He considered that Colonel Jackson had overstated the case in saying that the object of the Association was to canvass for subscribers for the New Telephone Company.

Mr. THOMPSON held that the present was not an opportunity for discussing the question; for, as Mr. Morse had pointed out, the agenda had not given any information which would have enabled members to obtain data on the subject. He thought it a pity that Colonel Jackson had gone out of his way to exaggerate the matter in any manner. He suggested that if it became a more burning question, and did not fall to the ground—which seemed probable—the matter should be more fully stated in a subsequent agenda paper, as that would enable members to attend the meeting, when the subject could be properly discussed from both sides. Of course there were two side to the question.

Colonel JACKSON said he regretted that he did not see Mr. Thomson, Mr. Haigh, and some other members of the Association present. He was quite certain that if they had been—for they were honourable and fair-minded men—they would see the impropriety of the affiliation of the Association with which they were connected with the Chamber, under the circumstances which he had described. As to Mr. Bennett's remarks, he (the speaker) did not choose to go into the past history of the Association. He had mentioned its present specific object as shown by its own circular. He proposed, "That considering that the Association for the Protection of Telephone Subscribers have undertaken the task, for a consideration, of canvassing for subscribers to the New Telephone Company, it should not be affiliated as an Association with the London Chamber of Commerce."

The CHAIRMAN said that the meeting would not have power to deal with such a resolution. It would be necessary for some representation to be put before the Council of the Chamber. The Section had only to do with its members, and not with the action of people who were not members of the Section.

Colonel JACKSON said he would add to his resolution "that it be submitted to the Council for the consideration of that body."

The CHAIRMAN: That is absolutely in order.

Mr. JENKINS seconded the motion.

Mr. THOMPSON proposed as an amendment, "That no action be taken by the Electrical Section in the matter of the Telephone Subscribers Association and the New Telephone Company at the present time."

Mr. ALBRIGHT seconded the amendment, which was carried by ten to seven.

The CHAIRMAN, in reply to Colonel Jackson, said that the amendment did not prevent the matter from being brought before the Council. The amendment was simply to the effect that the Electrical Section had declined, for the present, to make any representation. Continuing, he stated that the next business on the agenda was "The attitude of the Section towards the Parliamentary Committee who are to consider the whole question of electric railways in London." He thought that, as a matter of fact, all the railways had passed the Committee, and therefore he supposed there was nothing for them to do on the matter but to say "Thank you" to the Committee. The next business on the paper was "The action taken by the Chamber in reference to the question of overhead wires, and to consider the reply from the President of the Board of Trade."

Mr. MURRAY read the correspondence which had passed with the Board of Trade on the subject.

Mr. CROMPTON stated that if the reply of the Board of Trade were taken exactly as written, it would put them in rather a foolish position. It would appear as if they had gone to great pains to prepare the memorial referred to without any due cause; but it was very difficult to understand how the Board of Trade could have penned the letter of the 23rd of February, in face of the fact that it was at their own direct request—made to himself and another member of the Chamber, in the presence of a formal meeting, Mr. Courtney Boyle and his advisers, Major Cardew, and others—that they should ascertain the opinion of the trade on the subject, and if necessary, memorialise them. If that could be construed in any other way than that they should bring a memorial before them, there might be some sense in their letter. He thought, however, that they need say no more about the matter, having got what they wanted. He had only made these remarks with a view of showing that they had not proceeded without due justification.

The CHAIRMAN stated that the next matter to be dealt with was the bye-laws of the County Council in reference to overhead wires. He did not know whether any of the members present had anything to say on the question.

Mr. W. E. L. GAINE, of the National Telephone Company, thought he might explain the matter to the meeting. The bye-laws had been made by the London County Council only, but they were of no force until they were confirmed by the Board of Trade. The Board of Trade had now made an appointment to consider them and the objections of those who had any objections to make on the 28th of next month. He represented the National Telephone Company, and the question of overhead wires and the possible interference of the County Council was one not only affecting the interests of the Company and those running wires, but it was also a very large public question. He would therefore venture to suggest and, if necessary, move the appointment of a small committee of the Section for the purpose of considering the bye-laws, and also of hearing those whose interests were affected, and the public interests generally.

Mr. BENNETT seconded the motion, which was carried, the committee to consist of the Chairman and Deputy-Chairmen, Mr. Gaine, Mr. Bennett, and Mr. Henry Edmunds.

The CHAIRMAN said they had next to consider the question of electrical communication on the coasts. Since the agenda paper was prepared, the President of the Board of Trade had undertaken to make some temporary arrangement, and, therefore, he did not think that they could do anything practical in that matter that day. There was only one other question on the agenda

Digitized by Google

paper, namely, as to the co-operation of the Section with the new Mining Section of the Chamber. He was informed that the new Mining Section was a very large and important one. What was intended was simply a kind of token of good-will—that they might be introduced to the Section in order that if and when matters arose in any way common to the two Sections—the Mining Section and their own—they should meet.

Mr. SYDNEY MORSE afterwards proposed a resolution appointing a Special Committee to consider and deal with questions affecting the interests of the Section in regard to electric traction. There had, he said, been a movement for some little time in connection with the formation of some Association for the purpose. It had been suggested that if the matter were put into the form of a committee of the Section, it would have a great deal more influence and would appeal to a wider body.

Mr. GARCKE seconded the motion, observing that he regarded it as a matter of considerable importance, not only to the Section, but also to the industry generally. The proposal had been under discussion by several members that an Association should be formed to consider the questions relating to electric traction. He thought there was quite an unnecessary tendency to form separate associations. It involved expense to all, which might be avoided, and associations never had the same standing which they had under cover of the London Chamber of Commerce. He therefore seconded Mr. Morse's resolution with considerable satisfaction. The only question of importance in connection with the formation of such a committee was its constitution, which was a very important matter, and he ventured, therefore, to suggest that it should not be hastily decided upon. It was very desirable that the gentlemen who contemplated the formation of such an Association should be consulted, and, if they would do so, that they should serve on the proposed committee. For that reason he would suggest that it was very difficult for them at that meeting to determine who were the best and most qualified men to serve on such a committee, and that the matter be left to the consideration of the executive Committee, consisting of the Chairman and Vice-Chairmen, to report upon again.

The CHAIRMAN desired to say a word endorsing what Mr. Garcke had said. When they began the Section they all hoped that there would be no separate associations as regards their trade, and that they would be able to do all their business in connection with the Section. It was a matter of great regret to them that the supply companies had thought it necessary to form an Association. He believed that the Section would be of infinitely greater use if, whenever it was thought advisable for an Association to be formed, those who contemplated such a proceeding would communicate with the Section first to ascertain whether the Section could not do the work.

Mr. GAINE said that the unfortunate telephone company had come up again in regard to the resolution before the meeting. He would like to know what it meant. It was known to a great many members of the Chamber that a very difficult question arose when certain classes of electric traction were used upon tramways as between the electric companies and the telephone companies. That question had been, as, perhaps, many of them knew, threshed out before the Parliamentary Committee, with the result that certain protective clauses had been inserted in the interests of the telephone companies in the various Electric Bills before Parliament. What he wanted to know was whether the idea and intention of appointing the committee now proposed was to re-open a question which, he ventured to think, had been decided by Parliament.

Mr. THOMPSON, in support of Mr. Gaine, said he did not think it was desirable for the Section to commit itself to any decided line of action by any "snap resolution," such as that proposed. While he thought it desirable that the Chamber should take some action, yet, in proportion as the strength of the voice of the Chamber was as had been described, so it was important that they should not take any action without very careful consideration, and without the Section having an opportunity of carefully considering the subject. The matter was not upon the agenda paper, and therefore they could not have come to the meeting prepared with any data to enable them to discuss it. He therefore proposed as an amendment that the matter be left over to another meeting and be put upon the agenda paper. In the meantime they would have an opportunity of deciding who was best able sufficiently to represent the Section, and he thought they would serve their own interests in that way very much better than by taking a vote on the subject that day.

Mr. CROMPTON said he had heard that an Association was being formed which he thought it best to say at once would be antagonistic, to a certain extent, to the telephone interest; and it occurred to him that it would be very much better, and would be carrying out the objects of the Association, if the whole question were looked into from both sides by a full committee of the Section, consisting of members of both interests. He thought they should really see if a *modus vivendi* could not be arrived at by a number of business men sitting round a table, instead of confiding their interests to lawyers and electrical experts. He thought that any great delay in bringing together what he believed would be a friendly committee might be the cause of a great expenditure of money, great loss of time, and irritation between the branches of their industry, which might be avoided. He thought the telephone interest should be fully represented on the committee, and by their best men, in the same way that the traction interest should be represented by their best men; and he could not help thinking that they could, under such circumstances, arrange to try out this question—the use of the earth—under one chosen arbitrator, and so save the enormous expense which they saw looming in the distance. The question was going to be tried out in America, on the Continent, and here; and he thought they would do well in trying it out among the Section. For that reason he had been delighted to hear Mr. Morse bring the matter forward. He saw disadvantage in delaying the appointment of a Committee.

Mr. GAINE said he would have liked to fall in with Mr. Crompton's suggestion, because he believed that wherever possible conferences should be held. His position in the matter was this—that the question between the telephone companies and the electric traction companies had been thoroughly threshed out in Parliament. For the last two or three Sessions every Electrical Traction Bill had had a protective clause put in it by Parliament for the benefit of the telephone companies. He did not oppose the committee, but he could not go to that committee with any suggestion that the question, so far as they were concerned, was an open question—that was to say, he could not give up what, at very great expense, had been fully threshed out in Parliament. He thought there were only one or two cases in the country of statutory powers, obtained in earlier days, where such protective clauses for the telephone interests did not exist; and in one of those cases—Leeds—legal proceedings were pending as to whether without that protection the Telephone Company was not entitled to protection under the law of the land. The English of it was, which of the two companies was to double their wires. Let the committee be appointed; but, as far as the National Telephone Company was concerned, they could not go to that committee with any suggestion that they departed from the position they had taken up before the Courts and before Parliament.

Mr. BEAUMONT observed that the remarks of Mr. Crompton and Mr. Gaine seemed to lend importance to the resolution. No doubt, it was a subject of great importance, and he therefore thought that they ought not to be in too great a hurry to impose on the Chairman and the Vice-Chairmen still greater responsibility than they had done by asking them to decide right off what should be the formation of the committee to consider the question. He would second Mr. Thompson's amendment.

Mr. MORSE said it seemed to him that many members had entirely overlooked one most important point, namely, the powers of the proposed committee. Mr. Gaine spoke as if by joining the committee he would necessarily have to give up something which he might have; but the committee was simply asked to consider and report. If the trade as a whole could meet the telephone companies as a whole, and could discuss the matter, did any one mean to say that there was not a fair medium course that might be arranged? That was the object of the Association, and that was the object of the committee which the meeting was asked to appoint.

Colonel JACKSON said he had listened with considerable interest to Mr. Crompton's remarks on the proposal, and he concurred with that gentleman that it was desirable that the representatives of the two interests mentioned should meet in conference to see whether the differences between them could not be settled; but, of course, as Mr. Gaine had said, the telephone company could not undertake to give up its legal rights as a preliminary, or to lay its great industry prostrate before any other industry. Short of that, however, it was advisable that the representatives of the two interests should meet in friendly conference.

The CHAIRMAN observed that Mr. Thompson had rather suggested that the matter under discussion was not on the agenda, but they said "other business" in the paper. He must say respecting what had fallen from Colonel Jackson that no one would dream that any one going into the committee would give up any rights. It was, as Mr. Crompton had said, a matter of great importance that they should see whether a *modus vivendi* could not be arrived at among themselves, instead of having to put money into the pockets of lawyers and experts.

Mr. THOMPSON said he would propose a compromise. He was at one with Mr. Morse as to the first point in his resolution, but he would suggest that the *ex officio* members of the committee should in the meantime act.

After some further discussion the following resolution was agreed to:—"That a Special Committee be appointed to consider and deal with the questions affecting the interests of this Section in regard to electric traction, and to report from time to time to his Section."

Digitized by Google

Mr. THOMPSON then proposed "That the Chairman and Vice-Chairmen of the Section be the Committee, with power to add to their number such names as they may nominate, and submit to the next meeting for confirmation."

Mr. BEAUMONT seconded the motion.

Mr. CROMPTON said he would propose an amendment. The Committee could not get to work until it was formed with a full complement of members. It was a waste of time of a month to postpone, as had been suggested, the full nomination of the Committee; and he proposed "That the Committee be forthwith nominated by the Chairman and Vice-Chairmen."

The amendment was seconded, and put by the CHAIRMAN, who declared it carried.

The proceedings then terminated

THE GOVERNMENT AND THE TELEPHONES.

The following is a *précis* of the Bill introduced last week by the Postmaster General, entitled "A Bill to make further provision respecting Telegraphs."

Clause 1 states that, as it is expedient to raise money with a view to carry into effect the scheme of the Postmaster-General for the development of that part of the telegraphic system of the United Kingdom which is called the telephonic system, and, in particular, with a view to purchase and provide the main lines of telephonic communication, the Treasury shall, with this view, issue out of the Consolidated Fund such sums not exceeding in the whole the sum of £1,000,000, as may be required by the Postmaster-General.

Clause 2 stipulates that if the Postmaster-General considers that the inhabitants of any district, or any public authority, are debarred from the public convenience of telegraphic communication owing to the refusal of any person to consent to the construction or maintenance of a work by the Postmaster-General, the Railway and Canal Commission may be invoked; and that Commission, if satisfied, after holding a local inquiry, and giving an opportunity for all persons interested to be heard, that the inhabitants are so debarred, may make an Order consenting to the construction of the work, either unconditionally or subject to such pecuniary or other conditions as the Commission think just; and such consent shall, for all purposes, be of the same effect as if given by the said person. The Postmaster-General may introduce into Parliament a Bill confirming any such Order; and the Order, when so confirmed, with any modification made therein by Parliament, shall have full effect.

Clause 3 extends the provisions of the Telegraph Acts, 1863 and 1878, relating to streets, &c, within the limits of any town having a population of 30,000 inhabitants or upwards, to streets, &c., within the limits of any urban sanitary district.

Clause 4 relates to telegraph lines constructed irregularly or by persons other than the Postmaster-General, and extends the protective clauses of the Telegraph Acts of 1863 and 1878 to such lines. Sub-section 2 runs as follows:—

> Where, either before or after the passing of this Act, any consent for the construction of a telegraphic line along a street or public road has been given, subject to any term, condition, or stipulation, to a person through whom the Postmaster-General claims, the Postmaster-General may give a notice to the authority or person giving the consent asking for the withdrawal of that term, condition, or stipulation; and if the authority or person fail to withdraw it within twenty-one days after the notice is given, a difference shall be deemed to have arisen between that authority or person and the Postmaster-General, and shall be determined in manner provided by sections four and five of the Telegraph Act, 1878.

Clause 5 relates to licensees of the Postmaster-General, licensed to transmit any telegrams within the meaning of the Telegraph Acts, 1863 to 1889, and authorises the licensee during the time and within the area specified in the licence, to exercise the powers, so far as applicable to telegraphic lines above ground, which are conferred on the Postmaster-General by the Telegraph Acts, 1863 and 1878, and by the provisions of this Act relating to Provisional Orders, or such of those powers as are specified in the licence. A licensee is not, however, to exercise any of these powers without the consent, in London of the County Council, and in any urban sanitary district outside London of the Urban Sanitary Authority, and elsewhere of the County Council, and he will have to comply with any regulations of these authorities.

Clause 6 runs as follows:—

> (1) Any Company or person authorised to lay an electric line within the meaning of the Electric Lighting Act, 1882, may, with the approval of the Board of Trade, and by agreement with the Postmaster-General, or, if so authorised by the Postmaster-General, with his licensee, place, or authorise the Postmaster-General or his licensee to place, telegraphs in the trenches, tubes, pipes, or apparatus used for the purpose of such electric line.
>
> (2) The enactments relating to the Company or person in relation to the powers, operations, trenches. tubes, pipes, and apparatus of sueh Company or person for the purpose of the electric line shall, so far as applicable, extend to the said telegraphs, and to anything done in pursuance of this section.

Clauses 7 and 8 are respectively saving and extension of meaning clauses. Clause 9 contains various definitions. Clauses 10, 11, 12, relate to the application of the Act to Scotland, Ireland, and the Isle of Man. Clause 13 relates to the title of the Act.

TREASURY MINUTE.

The following Treasury Minute (dated May 23rd), upon the Proposals for the Development of the Telephone System in the United Kingdom, has been laid before Parliament:—

My Lords have before them the proposals of the Postmaster-General for carrying out the policy which has been adopted by Her Majesty's Government for development of the telephone system in the United Kingdom.

1. It is the object of these proposals, while preserving the property in the telegraphs, which has been paid for by the nation, to secure that expansion of the telephone system which is called for by public opinion and the necessities of commerce. It is impossible to continue the present system under which the telegraph revenue is seriously suffering, while, on the other hand, the extension of telephones is checked in a manner which cannot be permanently maintained.

The proposals of the Postmaster-General will enable the telephone companies and the Post Office to co-operate in services to the public.

2. The telephone companies are at present restricted to oral communications. The scheme prepared by the Postmaster-General will in one direction, as hereafter explained, remove that restriction, and it proposes the establishment of trunk wires throughout the United Kingdom.

3. Unless trunk wires are in the hands of the State, a monopoly, injurious to the public interest, would inevitably ensue, to the advantage of the Company which first laid down such trunk wires.

4. If, on the removal of the restriction to oral communications, the companies were allowed themselves to write down and deliver messages and a network of trunk wires were spread over the country by private enterprise, the distinction established by Mr. Fawcett between the business of the companies and of the Post Office would disappear, and rival systems of telegraphy would be working side by side where Parliament intended that there should be only one.

5. For this reason it is proposed that the Post Office shall write down and deliver the messages, and that the Post Office shall provide a national system of trunk lines. United action on the part of the companies and the Post Office is necessary to the success of the scheme.

6. It is proposed that the companies should abandon their right to construct trunk wires, and that the Post Office should purchase from them such as they have already erected; and that in addition to this the Post Office should gradually provide additional trunk wires, so that there may ultimately be a complete system of communication between all the important towns in the kingdom. It is further proposed that a connecting link between Great Britain and Ireland should be furnished by a submarine cable, and that the whole system should be open, not only to the subscribers of the companies, but also to any member of the public who may choose to come to a post-office for the purpose of using it.

7. The companies will connect their exchanges with the offices of the Post Office, in order that their subscribers may telephone messages—

(*a*) For transmission over the public telegraphs;
(*b*) For transmission through the post as letters;
(*c*) For delivery as express letters;
(*d*) That they may be for the service of express messengers; and may
(*e*) Request to be placed in telephonic communication with other towns by means of the trunk wires of the State.

8. The Post Office will make no charge for the service of its officers who attend to the wires connecting the exchanges with the local post offices, and will pay the companies a commission of 5 per cent. on ordinary telegrams telephoned to those offices for transmission by the public telegraphs.

9. The Post Office will withdraw its veto on the establishment by the companies of public call offices in the houses and shops of sub-postmasters. It will further be a consideration whether, if the convenience of the department will permit it, head, district, and branch post offices should be allowed to be used as call offices, &c., subject to such payment by way of rent as may be agreed on.

10. As far as practicable the Post Office will provide underground wires at an agreed rent to connect together the exchanges of a company within one and the same exchange area, so that municipal authorities may not have to complain of their streets being disturbed by the companies, which, in some places, might be in competition.

Digitized by Google

11. The Post Office, where it can permit telephone companies to use railways, canals, or other property, over which it has acquired exclusive rights of way for telegraphs, will charge a nominal sum of 1s. per mile of wire, instead of 20s. as at present.

12. Parliament, by a Bill now about to be introduced, will be asked to confer on the companies, subject to the consent of the local authority, powers for the erection of the wires required to connect their exchanges with the houses of their subscribers.

13. The messages telephoned to post-offices for delivery will have to be limited in length, and it is proposed to adopt the two-fold limit of three minutes and 30 words. The charge will be the same as for an ordinary express letter, viz., 3d., if the address be within a mile of the post-office where the message is written down.*

14. For conversations on the trunk wires of the State the following charges will, it is thought, be equitable, while, at the same time, sufficient to secure a margin of profit.*

For any distance not exceeding 20 miles	3d.
For any distance exceeding 20 miles and not exceeding 40 miles	6d.
For every additional 40 miles or fraction thereof	6d.

15. A charge of 6d. for 40 miles has been sanctioned by the Treasury for the trunk wires already provided by the Post Office; but the charge of 3d. for 20 miles is new. The Post Office consider it necessary that there should be this lower charge for the short wires.

Longer distances cannot be charged for at a less rate, as, although it is true that the terminal expenses are a fixed quantity, the expenses of construction and maintenance will, even in proportion, increase greatly with the length of the line. Where a submarine cable is used, or where exceptional expense is incurred, an additional charge will be made.

16. As in the case of the London-Paris telephone line, the period of each conversation will be three minutes, and two consecutive periods will be allowed for a double payment.

17. My Lords will examine with care such schemes as may be successively submitted by the Post Office for the gradual construction of new trunk lines.

In the course of a few months wires can be erected on existing poles from London to certain principal places, and progress can be made, as convenience permits, with further wires in many directions.

These works would be carried out in such a manner as to supplement and extend the system acquired from the companies.

18. It must be clearly understood that the right of the Post Office to establish telephone exchanges, which was reserved by Mr. Fawcett, will be maintained, the department holding itself ready, as in the past, to comply with the reasonable demand of any town or district for telephonic facilities.

19. As to fresh licences, no further licence for the whole country will be granted; and even for a licence to establish an exchange in a particular town no application will be entertained unless a formal resolution in its favour has been passed by the Corporation or other municipal authority, and evidence given that there is sufficient capital subscribed to carry out the undertaking. In this way competition will not be excluded, but a check will be imposed on the formation of companies whose sole object it is to force the existing licensees to buy them up.

But although this is the policy which commends itself to Her Majesty's Government, it must be distinctly understood that, should licences hereafter be granted on other principles, no Company now or hereafter to be licensed will have any ground to complain of breach of contract or want of good faith on the part of the Postmaster-General.

It will be a condition of any licence to a new Company that their system must be constructed entirely of twin wires or metallic circuits, so that there may be an assurance of its efficiency.

20. The royalties now payable by the companies to the State will remain unchanged. The other conditions imposed by their licences will remain unchanged, except so far as they may be modified by the policy indicated in this minute.

21. In conclusion, it may be stated that the intention is to meet, as far as possible, the views of municipal authorities, to aid the telephone companies in the improvement of their exchange system, to place additional facilities at the disposal of the public, and to establish trunk wires between the more important towns throughout the country.

My Lords concur.

* These charges are independent of the charges which the companies made on their own account for sending a telephone message.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—MONDAY, MAY 30TH.

The Great Northern and City Railway Bill.

Mr. PICKERSGILL moved that it be an instruction to the Committee on the Great Northern and City Railway Bill that they do insert a clause reserving to the London County Council a power to purchase the undertaking after the expiration of a limited period on terms similar to those provided in Section 43 of the Tramways Act, 1870. He urged that no difference should be made in this matter between tramway and railway companies, and he invited the House to declare the principle that the public should have the opportunity of purchasing this and other local railways after the expiration of a certain time.

Mr. WHITMORE hoped the House would not agree to the instruction. The Joint Committee which considered the group of Bills seeking to provide underground communication in the metropolis were satisfied that the acceptance of such a proposal would endanger the success of the scheme, because it would prevent the capital being subscribed. The Great Northern and City Railway, moreover, would not be merely a local line, but would supply a new terminus for the Great Northern system, and, consequently, it did not come in quite the same category as the other schemes.

Sir J. PEASE thought that this notion must have taken the House a good deal by surprise. The principle involved was a very large one—that all new railways constructed in the district of the London County Council should become, like tramways, the property of the County Council at the end of a certain period—and he hoped the House would hesitate before it sanctioned such a principle.

Mr. R. G. WEBSTER observed that the London County Council was such a grasping body that one was always in a state of wonder as to what it would ask for next. If the demands of the County Council were acceded to in these railway matters there would be an end of schemes which would provide a great deal of remunerative employment to the working classes. The London County Council was a municipal cuckoo. It introduced no great schemes of its own and tried to interfere with those of other people. The proposal before the House was quite unworkable, and he trusted it would be rejected.

Mr. HOWELL supported the motion, believing that it would result in advantage to the metropolis. He looked forward to the time when the management of the railways would be taken over by the State.

Mr. KIMBER thought that this proposal was made by the County Council in the hope of being able ultimately to direct and control all the labour of London. It wished to command the army of labour in order to acquire the suffrages of the masses for a particular party. If the proposal before the House were agreed to they would certainly receive similar applications from large and small provincial towns and would not be in a position to refuse them.

Mr. COURTNEY opposed the motion on the ground that the proposal was disapproved by the Joint Committee of Lords and Commons who had considered the subject.

Mr. J. S. GATHORNE-HARDY explained the reasons which had led the Committee to the conclusion that the plan was inexpedient.

Mr. PICKERSGILL explained that, although he was authorised by the County Council to move this resolution, yet, in deference to the views of the hon. member for Chelsea, he did not intend to press it, but would take a division upon the next resolution.

The resolution having been by leave withdrawn,

Mr. PICKERSGILL moved a similar resolution with reference to the Central London Railway Bill,

The House divided, and the numbers were—

For the resolution	83
Against	127
Majority against	—44

The resolution was therefore rejected.

TUESDAY, MAY 31ST.

Select Committee on the Electric Railway Schemes.

The Select Committee of the House of Commons, which has been appointed, with Sir John Kennaway as chairman, to consider the various schemes for providing underground electrical railway communication in different parts of the Metropolis, held their first meeting on Tuesday, May 31st. The first scheme dealt with by the Committee was that of the proposed Baker-street and Waterloo Railway.

The promoters of the Bill were represented by Mr. Pember, Q.C., Mr. Cripps, Q.C., and Mr. Francis; and the numerous opponents were represented as follows:—The Metropolitan Railway Company by Mr. Littler, Q.C., and Mr. Worsley Taylor, Q.C.; the South-Eastern Railway Company also by Mr. Littler and Mr. Worsley Taylor, in addition to Mr. Tufton; the London County Council by Mr. Freeman; the Trustees of the Constitutional Club by Mr. A. G. Rickards; the National Liberal Club Buildings Company by Mr. Erskine Pollock, Q.C.; the Conservators of the River Thames by Mr. Littler, Q.C., and Mr. Claude Baggallay; the Vestry of St. Martin's-in-the-Fields by Mr. Meysey Thompson, Q.C.; and the Gordon Hotels Company (Limited) by Mr. Pope, Q.C., and Mr. Freeman. Other opponents to the Bill, who did not appear by counsel, were the vestries of Marylebone and Lambeth, the Metropolitan District Railway Company, the Union Bank of London, the Sun Insurance Company, the Hotel Victoria, and the County Fire Office.

Mr. PEMBER, in opening the case for the promoters, explained that the Bill proposed to constitute an independent Company with a capital of £1,250,000, to make a line two miles seven furlongs in length, of which it was estimated the cost would be £990,000. In addition to the stations at the termini it was proposed to place stations at Charing Cross, Piccadilly Circus, and Oxford Circus. He pointed out that practically the lines proposed had received to some extent the sanction of Parliament through the report of the Joint Committee; and he therefore asked whether it was necessary to overlay the case with fresh evidence, or whether the natural and wisest course would not be to assume that there had been a *primâ facie* case made out for the line, and to call only formal evidence, and then to deal with the objections which were raised by the opponents as reasons why the line should not be made.

The CHAIRMAN said that before deciding that point the Committee would like to know what the petitions were, and the nature of the objections raised.

Mr. PEMBER thereupon dealt at length with the various petitions against the Bill; and at the conclusion of his speech,

The CHAIRMAN said that the Committee concurred in the report of the Joint Committee, that it was desirable that some means should be taken to relieve the congested and over-crowded streets of the Metropolis, and to open a communication between the north and south of London. On those points they would not require evidence.

Digitized by Google

Mr. PEMBER said that some of the petitions raised a question as to the value of electricity as a motive power. He did not know how far the Committee would desire evidence on that point.

The CHAIRMAN said he thought it would be desirable to have some evidence on that point. It would be very easy to put the existing Electrical Railway in the box, as it were.

Mr. PEMBER said that Mr. Greathead would be able to give any evidence on that point.

Mr. J. H. GREATHEAD was then examined by Mr. Francis, and said that, in addition to being engineer for the Liverpool Overhead Railway and the City and South London Line, he was engineer, in conjunction with Mr. Galbraith, for the present scheme. The only practical communication along the route was by omnibus, which was inconvenient and very slow, and the proposed railway would be three times as expeditious as the omnibus. The sharpest curve on the line would have a radius of four chains, there being several of that kind which compared favourably with the curves on the City and South London, which were worked with perfect safety. The steepest gradient would be one in 55, as compared with that on the South London of one in 30. The depth below the surface would vary from 85ft. at Oxford-street, to 15ft. at Waterloo, and the Thames would be passed under at a depth of 16ft. 6in. below the bed of the river. The deviation clause would allow them to go as much deeper as they liked, but there were limits above which they could not raise it. On the north side of the Thames the line would be for the most part in London clay, and on the south side it would pass into the overlying strata of gravel and sand, but there would be no difficulty whatever in tunnelling in either strata without any disturbance of property overhead. He described the mode of tunnelling by means of a shield, and said that to avoid any possible danger it had been decided by Sir John Fowler, Sir Benjamin Baker, and himself, in the Central London line, to also construct the station tunnels by means of shields, and the same course would be followed with this line. Referring to the City and South London line, he said that for 18 months they had run nearly 350 trains a day, and though there had been some slight hitches and delays, the traffic had been on the whole conducted in such a way as to compare favourably with the general suburban traffic on most of the railways, especially during the early part of the year, when on other railways the fog was so dense that it completely upset the working of other lines. There could be no question as to the advantage of electricity as a motive power. In addition to the £930,000 for the cost of the line, including contingencies, £300,000 would be required for rolling stock, hydraulic lifts, electric plant, and so on. He explained the mode of ventilation, and said that it was anticipated the line would carry 14,000,000 passengers a year.

Mr. LITTLER cross-examined the witness as to the possible interference with the Metropolitan St. John's Wood Railway line in case they should require either to widen or to carry another line beneath their own; but Mr. Greathead denied that the electric line would interfere with any such projects if contemplated, and said he was not aware that the South-Eastern Company had, for many years past, been considering the best method of themselves getting across London so as to get a junction of the Northern with the Southern lines. On the City and South London line more trains could be run if they had more rolling stock than at present.

Mr. LITTLER called attention to the fact that this Company had a large amount of unissued capital, and asked how it was they did not provide themselves with more rolling stock.

The CHAIRMAN said the Committee were not inquiring into the financial policy of the City and South London Company.

Mr. LITTLER: But if the line is running trains every 4½ minutes instead of every 2½ minutes, and I show that it is only earning £9,454 a year, whereas to make it pay decently it ought to earn £40,700, that surely is a matter to be considered. This is a line of about the same length, to be worked in the same way and for precisely similar purposes. This question was not gone into before the Joint Committee because the Joint Committee did not think it worth their while to be assisted by those who knew most about the matter, namely, the solicitors and managers of the railways.

At this point, by special request, Mr. Charles Scotter, general manager of the London and South-Western Company, was interposed as a witness, and gave general evidence in favour of the line and its prospects of traffic In reply to Mr. Pope he said the South-Western Company were not giving any financial assistance to the promoters.

Mr. GREATHEAD was then further cross-examined by Mr. Pope as to the treacherous character of the ground beneath Northumberland-avenue, but he would not admit that there was anything "ticklish" or "risky" about the operation of tunnelling there. Working with compressed air was very much more difficult and expensive.

Mr. POPE: Not so much as letting down the Hôtel Métropole. Where is your capital to come from if you do let it down?

Mr. FREEMAN said the County Council were also dissatisfied with the provisions as to the manner in which the work was to be carried out under Northumberland-avenue.

The CHAIRMAN: Are you prepared to submit any provisions which would satisfy them?

Mr. FREEMAN said that he would consult his clients on the matter.

The Committee adjourned till Wednesday.

WEDNESDAY, JUNE 1ST.

At the sitting of the Committee on Wednesday Mr. PEMBER announced that to meet the objections of the trustees of the Constitutional and National Liberal Clubs, the Gordon Hotels (Limited), Hotel Victoria, and other petitioners in Northumberland-avenue, having regard to the exceptional character of the buildings, the promoters had drawn up a clause which provided that "the railway and station tunnels other than the shafts and approaches to stations shall be constructed between the statue of King Charles I. at Charing Cross and the north side of the river Thames at such a depth that the exterior surface of the crown of the tunnel shall be not less than 10ft. below the surface of the London clay; but this provision shall not apply to the case of short pockets or pot holes in the clay if such are met with in the line of the railway extending below the general surface of the clay;" and that "prior to commencing any part of the works situated between the points aforesaid the Company shall make trial borings throughout the entire line of the proposed tunnels between the points aforesaid for the purpose of ascertaining the nature of the soil through which the tunnels are to be constructed, and, if the engineer to be appointed by the petitioners shall so require the whole or any part of the railway between the points aforesaid shall be constructed under compressed air." The engineer to the petitioners is to have liberty of inspecting the works, "and if such engineer shall be of opinion that the construction of the works or other operations of the Company are attended with danger to the property of the Northumberland-avenue petitioners, the Company shall forthwith adopt such additional measures and precautions, including additional borings, as may be considered necessary for the purpose of preventing damage or injury." Compensation is to be paid for any structural damage, and no generating station is to be constructed within 100 yards of any of the properties in Northumberland-avenue.

Mr. POPE, for the petitioners, intimated that the clause would afford a satisfactory basis of agreement; and later in the day it was announced that an arrangement had been come to.

Mr. J. H. GREATHEAD was recalled, and in reply to further questions in cross-examination stated that it was proposed to place the electrical generating plant on the south side of Waterloo Station. There would be no interference with the Metropolitan sewers, or with the Thames Embankment wall. The average speed at which the trains would run would be 18 miles an hour. In re-examination by Mr. Pember, he said they proposed, on the Baker-street-Waterloo line, to spend three times as much on equipment as was spent on the City and South London Line. The Baker street tunnels would be larger, and the stations longer; and, if all the capital powers were exercised, the cost would be £550,000 a mile, as against £250,000 to £300,000 a mile on the City and South London. He considered that his estimate of 14,000,000 passengers over the three miles of line per annum to be reasonable; and, at an average fare of 2d. a passenger, it would pay a dividend of 4 per cent. When the Metropolitan Railway was a short line of 4½ miles it carried 5½ million passengers per mile.

Mr. W. R. GALBRAITH, joint engineer to the line, gave further details as to the method of construction, the necessity for the line, the amount of traffic that it would command, and the absence of interference with properties. The promoters, he said, would be prepared to make an access between the Metropolitan Station at Baker-street and the station of the proposed line, which would be a convenience to the public and an advantage to the Metropolitan Company. They would also desire to have a station on the south side of Regent's Park, near Portland-road Station, but they were under an obligation to the Crown not to break the surface of the Park. At Charing Cross, opposite the Nelson Monument, land had been scheduled for a station; but they did not intend to make one there unless they were driven from the other end of Northumberland-avenue.

This concluded the case for the promoters.

Mr. LITTLER addressed the Committee on behalf of the Metropolitan and South Eastern Railway Companies, stating that the report of the Joint Committee would have more force if they had allowed the parties to be represented before them. The line, he said, would be absolutely and totally useless for ordinary railway traffic; was a useless and stupid line, and would carry next to no traffic. He referred to the experience of the City and South London line, which carried only 14 passengers per train mile, or 42 passengers per trip on the average, and asked if that was a result likely to encourage anyone to invest money in this line, even if it were authorised. The net earnings on the South London last half-year were only £4,727, out of which £4,304 was absorbed by interest on the debentures, and £150 on preference shares, which left a magnificent total towards paying dividend on capital of £301. That was the financial result to those who had been foolish enough to be entrapped by prospectuses into putting their money into the line. The learned counsel had not concluded when the Committee again adjourned.

LEGAL INTELLIGENCE.

The Lane-Fox Patent: Petition for Prolongation.

The Earl of Selborne, Lord Watson, Lord Hannen, and Lord Shand, sitting as members of the Judicial Committee of the Privy Council, on Saturday had before them the case of Mr. Lane-Fox's Patent in the form of an application to fix a date for hearing the arguments and evidence in favour of the prolongation of the patent. When the case was called on by the Registrar, the Earl of Selborne said their Lordships would sit to hear this case on Thursday, July 7th.

Western Counties and South Wales Telephone Company (Limited) v. Bournemouth and District Electric Supply Company (Limited).

In the Chancery Division, on Friday last, the case of the Western Counties and South Wales Telephone Company v. Bournemouth and District Electric Supply Company again came before Mr. Justice Chitty in the form of a motion asking that a writ of sequestration might issue for an alleged contempt of Court by the Bournemouth and District Electric Supply

Digitized by Google

Company in wilfully disobeying an order of the Court, made on the 8th of April last, directing that the defendants should be perpetually restrained from working or using their electric lighting system, apparatus, and works in the town and neighbourhood of Bournemouth, in such a manner as to injure or interfere with the plaintiff's exchange system, and in particular from causing or permitting injury to the plaintiffs' system, either by induction or leakage, or from any other cause connected with the defendants' conductors.

Mr. FARWELL, Q.C., who supported the motion on behalf of the plaintiffs, said after the order of the 8th of April had been made the defendants applied to his clients to suspend its operation in order that they might have time to complete their work, and the plaintiffs acceded to their request, giving them until April 22nd. Subsequently the plaintiffs further extended the time to enable the defendants to remedy the defects in their system till May 6th. On May 5th a disturbance commenced which had continued. It commenced when the defendants' electric current was turned on, and it ceased when the current was turned off. The defendants had admitted that the fault was theirs. They said that their lines were in the first place improperly laid down, and in consequence of their not being allowed sufficient time to do the work properly; but that now their system had been improved. He (the learned counsel) believed that there had been some improvement, though there was still a disturbance, and the plaintiffs' subscribers continued to complain. Some were threatening to withdraw their subscriptions because, they said, it was useless for them to go on unless the disturbance was effectually stopped. The defendants had placed their wires underground, but that had not cured the disturbance of which the plaintiffs complained. He had several affidavits in support of the plaintiffs' case, that their telephone system was seriously interfered with by the electrical disturbance due to the defendants' electric lighting apparatus. On Thursday, May 5th, after the defendants' electric current had been turned on, the disturbance was so serious that it rendered the plaintiffs' telephones useless. Unless this serious disturbance was put an end to forthwith, it would be useless for the plaintiffs to attempt to carry on their business at Bournemouth, Poole, or Christchurch. He believed that if the defendants had constructed their underground lines with proper care the disturbance would have been avoided, as in every other place where the two systems worked together. Mr. Alfred Haynes, a chemist of Bournemouth, in his affidavit, stated that the disturbance on the line connected with his premises had been intolerable. In the day time there was no interruption whatever, but immediately the defendants' electric current was turned on there was great buzzing in the telephone, which had rendered it impossible for him to use the instrument.

His LORDSHIP: How does the disturbance arise?

Mr. FARWELL: From induction or leakage.

Mr. BYRNE, Q.C., who represented the defendant company, said his clients had complied with the regulations of the Board of Trade in every respect.

Mr. FARWELL, continuing, said: The issue his lordship had to try was whether the defendants were responsible for the disturbance which undoubtedly existed.

His LORDSHIP inquired whether it was suggested that the plaintiffs should do anything.

Mr. FARWELL replied in the negative. Prof. Silvanus Thompson, however, said that a return wire was desirable in the plaintiffs' telephone system. The defendants had filed several affidavits in support of their case. Mr. W. M. Mordey stated that on the 25th of May he took the opportunity of listening at the telephone at his hotel and at the defendants' works while there was a good deal of summer lightning about, and found that each flash was accompanied on the telephone by a rapid crackling noise, which was very disturbing, rendered talking difficult, and afforded a striking instance of the way in which a telephone system with earth returns was affected by all kinds of electrical effects. The defendants electric light machinery was at work and caused a faint hum, but it did not interfere in any way with conversation. Prof. Silvanus P. Thompson stated that he visited Bournemouth on May 23rd, and listened through the plaintiffs' instruments during the evening when the defendants' electric light system was in operation, but could not detect any disturbance worth naming or that interfered in any material degree with the operations of the plaintiffs' system. He spoke through the telephone from the Hotel Mont Doré and also through the telephone from the exchange to the defendants' works in the Bourne Valley. There was a faint hum like that to be heard in a sea shell when held close to the ear, which was doubtless caused by the defendants' lines; but the talking to both places was carried on without the slightest difficulty. There were occasionally stray noises, but those were not due to the electric light circuits. There was the well-known crackling sound due to the plaintiffs' carbon transmitters, and there were occasionally whizzing sounds due to the use of electric bells on other lines in the plaintiffs' system. He spoke through several times, and talking went on unimpeded. He knew of no reason why the humming sound should have been worse than it was on the occasion of his visit, unless there had been a leakage of electric current from defective joints, now removed from the circuits. He thought such leakages were excusable where the work had been done at high pressure. The noise was far worse on the London telephone exchange, where the hum was more distracting than at Bournemouth, and yet business was done. It was well known that such humming and stray sounds would be avoided by the use of proper metallic return wires, as was done in all modern exchanges. He referred to the telephone exchanges at Newcastle and Manchester as examples of modern exchanges in which there was no possibility of humming, cross-talk, or any interference from stray currents. Stray currents, whether arising from telegraphs or electric lighting, or from the natural earth currents which flowed in the coil, were certain to be picked up by the old-fashioned system that employed the soil of the earth instead of proper return wires. Where such metallic returns were not employed, disturbance was, in his opinion, inevitable. The defendants were doing all they possibly could not to interfere with the plaintiffs' exchange. Speaking generally, he could state confidently that conversation could be carried on at Bournemouth on the plaintiffs' lines with far greater comfort and ease than was the case in most districts in London. Mr. J. C. Bailey, electrical engineer at Bournemouth, in his affidavit, stated that he inspected both the plaintiffs' and the defendants' lines on the 4th inst., and that he found the plaintiffs' lower wires had been carelessly fixed. They were slack and appeared to be temporary wires. There was a good deal of wind, and plaintiffs' wires were blowing against their own stays, and also against the stays of the defendants, and in some cases the wires were resting on the roofs. All these things would cause disturbance in the telephone. The defendants' wires in the same place were in good order, high up above the telephone wires, and properly strained, so that there could be no contact. Mr. Alfred Jolliffe, house and estate agent of Bournemouth, stated that he was one of the earliest subscribers to the telephone exchange. He had not noticed that the telephone communication was worse after the electric light was introduced into Bournemouth than it was before that time. Mr. Alfred Vale, of Bournemouth, stated that the communication through his telephone had been imperfect at times, but he had not noticed any additional disturbance after the electric current had been turned on. The plaintiffs had filed affidavits in reply. Mr. James Swinburne stated that he went to Bournemouth on Wednesday, May 18th, and tested the various telephone circuits, and found the system very satisfactory. There was little or no cross talk. In some cases he thought there were some slight evidences of imperfect contacts, as men were at work on them, and had coupled them temporarily. The telephone system appeared to him to be admirable. He called up the electric light station No. 225, and found the circuit very good. When the defendants' electric current was turned on at eight o'clock he again listened to the various circuits which he had already tested, for there was a hum in all of them, undoubtedly due to the electric light circuits. In all cases, however, it was possible to speak without interruption. The noise was a drawback, and would interfere with conversation between ordinary subscribers, who were not accustomed to the use of telephones as he was, and cause annoyance. Mr. Charles Goldston, electrical engineer, and chief superintendent of the electrical telegraphs, telephones, and lighting of the South-Western Railway, also stated that he went to plaintiffs' telephone exchange on the 18th of May, and at once tried the working of many of the telephone lines. He found them free from disturbance at 3.20 p.m.; but at 8.15 p.m., after the defendants' current had been turned on he discovered a very considerable amount of humming noise on all of them. After having tried nearly the whole of the wires he came to the conclusion that it was caused by the defendants' current. The learned counsel stated that he had other affidavits to a similar effect. He submitted that it was useless to come to the Court for an injunction at all if defendants were allowed to go on creating a state of things which was worse than that which existed before the action was commenced. It would be seen from the affidavits, that the defendants did not deny that a disturbance existed, but they tried to minimise its extent. That question had been fairly dealt with by the evidence of the plaintiffs' experts, including that of Mr. Goldstone. It was true that the defendants had set up the opinion of Prof. Silvanus Thompson, but that gentleman was not everybody. He submitted that the evidence of plaintiffs' witnesses was quite as credible and weighty as that of Prof. Silvanus Thompson, whose idea of the necessity of a return wire was quite negatived by the plaintiffs' evidence. As regards the point that the injunction which had been granted extended to only overhead wires, he maintained that it applied to all wires, and asked that if his lordship was of opinion that the defendants had wilfully disobeyed the order of the Court he should grant the order for which he applied.

His LORDSHIP said he supposed the plaintiffs did not want the sequestration to go at once?

Mr. FARWELL replied in the negative. He said he only required it to hold over the defendants' heads. If, however, the defendants did not enable the plaintiffs to satisfy their subscribers within a short time, he should certainly ask his lordship to enforce it.

Mr. BYRNE, in opposing the motion, denied that the defendants had wilfully disobeyed the order of the Court. In reference to public undertakings of this nature, there were certain things to be observed arising under the Statute in regard to the regulations of the Board of Trade. Originally the defendants' wires were overhead, and then they were in this difficulty, that in order to comply with the Board of Trade regulations they had to put their wires underground. They obtained time to make the alteration, but the plaintiffs put great pressure upon them, with the result that they were obliged to work night and day to get the work done. He asked his lordship to look carefully at the evidence which the defendants had put in, and then say whether it could reasonably be contended that a nuisance was going on, and that it had been wilfully committed by the defendants.

His LORDSHIP said the defendants were restrained generally from causing injury to the plaintiffs' system. Of course the injury must be something appreciable.

Mr. BYRNE submitted that the nuisance must be something substantial.

His LORDSHIP said it occurred to him that there was something like an admission on the part of the defendants that owing to the haste and hurry in which they had been compelled to do their work, it had not been completed in the same manner as it would have been if there had been no such haste and hurry. Perhaps the defendants required a little more time.

Mr. BYRNE said the defendants' case was that there was no nuisance.

His LORDSHIP thought that there was evidence on the part of the plaintiffs that the defendants caused a disturbance even now.

Mr. BYRNE said there was some evidence, but he maintained that the evidence to the contrary by the defendants' witnesses was stronger. That, however, was not the point. He ventured to think that the point at issue was whether the defendants had been acting wilfully.

Digitized by Google

His LORDSHIP suggested that if the defendants took a little more time they might satisfy the plaintiffs, and then the only question which would be left would be one of costs.

Mr. BYRNE asked his lordship to send down to Bournemouth an electrician of experience to examine the two systems, and to report to his lordship whether there was an appreciable annoyance, and, if so, what ought to be done by the defendants.

His LORDSHIP thought that the parties might agree upon an electrician who would make a report to him on the subject.

The case was accordingly adjourned *sine die*, to enable an electrician, to be agreed upon by the parties, to examine the plaintiffs' and defendants' systems and to report to the Court.

Clough and Co. v. The National Electric Supply Company.

This action was tried before Mr. Justice Day on Wednesday, in the Queen's Bench Division. It was to recover a sum of £120 for charges in connection with the obtaining of a loan of £5,000, acting as accountants, &c. The defendants paid £70 into court in settlement; but after hearing the evidence his lordship found for the plaintiffs with costs.

Akers v. Iliffe.

Before Justices Mathew and Wright, sitting as a Divisional Court, in the Queen's Bench, on Tuesday last, this action was tried. It was an appeal from a decision of Mr. Justice Denman, refusing to direct the plaintiff to give better answers to certain interrogatories in an action in which damages were claimed for alleged fraudulent representations in connection with the sale of an electrical business to the plaintiff for £5,000, the alleged misrepresentations consisting in the statements that the business carried on at Princes-street, London, W., was distinct from that carried on at Chalk Farm, London, N., and further that the net profits of the business for the year 1890 were £2,442. The defendant denied that such representations had been made by him, or by a Mr. Moat on his behalf. In the result the Court dismissed the appeal with regard to all the answers, excepting as to whether it was not a fact that the business at 17, Princes-street had been carried on since the purchase by the plaintiff, under the style of Charles Moat and Co., and as to the names of the partners in that firm.

CORRESPONDENCE.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is a great pity that members of the Institution of Electrical Engineers are practically unable either to read the Paper before it is formally read before the meeting, or to possess in their hands a copy of it during the time that it is being read. It is true there are some few proofs distributed before the meeting; but a great many members, who would otherwise take an intelligent interest in the business of the evening, are obliged to sit in uncomfortable and silent wonder owing to their being unable to gather the chief points of the Paper from the formal reading. The result is that the discussion severely suffers, and degenerates into a string of mere platitudes alternating with tangential flying into side issues. Members will not commit themselves to serious discussion or criticism till they have very much more information on the Paper than can be gathered from a single hearing. At the last meeting the discussion principally comprised a number of doubts as to whether the Newcastle Company can pay ten shillings a week or nothing at all for skilled management, and whether open-circuit transformers take more magnetising current than the closed-circuit ones (a question altogether at a tangent to the issues of the Paper). Many points of vital importance were entirely overlooked in the discussion, and presumably for the reasons I have already stated. Failing the confidence which is begotten of an intimate acquaintance with the Paper, I abstained from making a criticism, which I now beg the use of your columns to enable me to publish. On the wall near where I sat were a number of indicator diagrams from the Robey engines used at the Newcastle station, diagrams which plainly showed that there was something very wrong with the low-pressure valves of those engines. I gathered from the Paper, and have since verified, that owing to the irregular running of these engines the Mordey-Victoria alternators cannot be run in parallel; and that it is proposed to supply a more even torque to the pulleys either by means of a heavier flywheel or by running the whole power through springs placed between the shafting and the pulley! Now this would be clumsy, if not positively dangerous; and, in view of those indicator diagrams, is probably unnecessary. It is evident that there is a great deal too much compression in the low-pressure cylinders; there is, in fact, an enormous amount of over compression. Further than this, the steam is supplied to the low-pressure cylinders with too much wire-drawing. These defects are very noticeable at full load, but are even more so at light loads. I believe that if the Meye expansion valves on the low-pressure cylinders were reset so as to reduce the compression to at most one-third of what iti now, and if the steam were admitted with less wire-drawing there would be no difficulty whatever in getting the engines to run the alternators in parallel. I need not add that this would be a much more effective and economical mode of procedure than either of the ones suggested. One reason why the Robey engines at Newcastle are taking so much steam per unit supplied is because so much is wasted by inaccurate valve-setting. There may be losses in the transformers which are serious, and the low-tension system may or may not be more efficient, but in any system of distribution more energy is lost between the stoker's shovel and the dynamo pulley than anywhere else. One way to reduce these station losses is to look to the engine valves. That admirable engine-stethoscope, the indicator, often reveals malignant *consumption* in the lungs of the engine; and the only way to cure this expensive disease is to carefully reset the valves.—Yours, &c., E. T. CARTER.

29, Douglas-road, Willesden, N.W.
May 28, 1892.

ELECTRIC LOCOMOTIVES: A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A passage in the newly-published fourth edition of my "Dynamo-Electric Machinery" requires correction, being technically inaccurate. On p. 616 the statement occurs that the electric locomotives of the South London Electric Railway are now being replaced by some of Messrs. Siemens's locomotives. In justice to Messrs. Mather and Platt, it ought to be stated that the fourteen original locomotives supplied by them are still running, and that they have run in the aggregate not less than 450,000 miles. The two more recent locomotives supplied by Messrs. Siemens do not replace, but are supplementary to the original engines.—Yours, &c.,

June 1, 1892. SILVANUS P. THOMPSON.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The Caledonian Railway Company invite tenders for various stores for twelve months from August 1st next. A list of these stores will be found in our advertising columns. Specifications and tender forms may be obtained on and after June 6th of Mr. J. Lorimer, Caledonian Railway Company, Charles-street, St. Rollox, Glasgow, where also patterns may be inspected. Tenders must be lodged with the Secretary, Mr. J. Blackburn, 302, Buchanan-street, Glasgow, not later than Monday, June 20th next.

——The Bristol Urban Sanitary Authority are inviting tenders for the supply, delivery and erection of condensers, pumps, steam and other pipes at their Electric Lighting Station, Temple-back, Bristol. Tenders have to be sent in by Friday, the 1st July next. Plans and sections of the Station may be seen at the offices of Mr. Henry Williams, 21, Clare-street, Bristol, and copies of specification and tender form at the offices of the Sanitary Authority, on and after Wednesday, June 8th. Mr. D. Travers Burges, of 51, Prince-street, Bristol, is Town Clerk. Further particulars are given in our advertisement columns.

——— The North-Eastern Railway Company invite tenders for the supply, for the six months ending December 31st, of telegraph apparatus and telegraph wire and line stores. Tenders must reach the Secretary by noon on Tuesday next, the 7th inst.

——— The Local Board of Bishop's Stortford invite tenders for lighting the public streets at present lighted for a year from August 16th. Tenders must be sent to Mr. W. Gee, the Clerk to the Board, not later than 10 a.m. on the 18th inst.

Digitized by Google

TENDERS INVITED.—The Hull Corporation invite tenders for the supply of an overhead travelling crane for the electric light station. Tenders are to be in before noon on Friday next, the 10th inst.

——— The municipal authorities of Zamora, Spain, desire tenders for lighting the town by 100 20-c.p. and 220 16-c.p. incandescent lamps, and 14 1,200-c.p. arc lamps. Tenders to be opened on June 29th.

TENDERS ACCEPTED.—The tender of Messrs. Woodhouse and Rawson United, Limited, for wiring and fitting the Borough Surveyor's office at Huddersfield, has been accepted.

——— Messrs. Woodhouse and Rawson United (Limited) have secured the contract for supplying the machinery and plant for softening the water for the St. Helen's Corporation Waterworks. The amount of the contract will be £10,000.

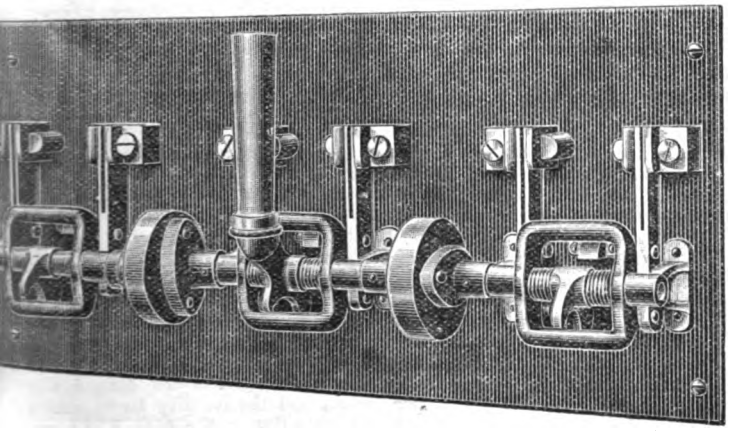
——— The tenders of Messrs. D. Hulett and Co. (Limited), Messrs. Evered and Co. (Limited), and the Phosphor Bronze Company (Limited) were amongst those accepted by the London County Council on Tuesday for the supply of brass and gun-metal goods and gas fittings for one year from the 1st prox.

APPOINTMENT VACANT.—The Gas Committee of the Manchester Corporation are prepared to receive applications for the position of clerk of the works, to superintend the construction and erection of the dynamos, engines, boilers, and other apparatus, and the laying of the mains and conductors, in connection with the electric installation. Applications must be sent in on or before the 24th inst. Particulars will be found in our advertisement columns.

DISSOLUTION OF PARTNERSHIP.—We are informed that the partnership hitherto existing between Messrs. E. H Cadiot and F. Espir has expired by effluxion of time. The business has been transferred to Mr. Fernand Espir, who will collect the whole of the assets and discharge all the liabilities of the late firm.

TELEPHONE AMALGAMATION.—The business of the Universal Telephone Company has been taken over by the National Telephone Company (Limited).

D. AND S. TRIPLE-POLE MAIN SWITCH.—A new form of main switch, to break three circuits simultaneously, has recently been introduced by Messrs. Dorman and Smith, of Manchester. This is illustrated herewith, and, as will be seen, consists of three of the double



Main switch for three-wire system.

break sudden-release B-type main switches, coupled together on an insulated shaft, and opened and closed by a single handle. The design is particularly strong, and there is no reason why these triple-pole switches should not meet with the success which has been met with by the double-pole design of a similar type.

MESSRS. CHARLES CHURCHILL AND CO. (LIMITED).—A handsome volume is to hand from this firm, containing illustrations, prices, and full particulars of their well-known American machine tools. The book forms a most complete catalogue; it contains many hundred illustrations, and consists in all of 320 large quarto pages. The book is prefaced by a complete index, and Messrs. Churchill and Co. intimate, in the introduction, that they will supply extra copies of any of the pages specially required.

ELECTRIC LAUNCHES ON THE THAMES.—We are asked by Mr. W. S. Sargeant to correct a statement made in our Trade Notes last week as to his being the builder of the electric launch "Myionu." Mr. Sargeant informs us that he designed and moulded the boat whilst acting as Manager for Messrs. Woodhouse and Rawson United (Limited).

MESSRS. WOODHOUSE AND RAWSON UNITED (LIMITED) have opened a branch for the Midlands at Minories, Birmingham, and have taken over the show rooms recently occupied by the Midland Electricity Company, together with the supply trade of that firm. We are asked to state that Mr. W. S. Sargeant has no longer any connection with this firm.

SALE BY AUCTION.—Messrs. James and Lister Lea and Sons, Birmingham, announce in our advertisement columns that they will sell by auction, on the premises, on June 20th to 24th, the valuable plant and machinery of Tranter's Gun Factory, Aston Cross, Birmingham, comprising 360 machines and lathes, steam engines, hydraulic tube drawing machine, a 50-ton Tangyes press, &c. They also announce that the works are to let.

WETLEY ABBEY, STOKE-ON-TRENT.—The Manchester branch of the Brush Electrical Engineering Company have put down plant for electric light at the residence of J. Hardman, Esq., which is noteworthy in that it demonstrates the success with which electric lighting can be carried out in a country mansion, with a petroleum engine as the prime motor. The plant consists of 60 16-c.p. lamps, with a battery of accumulators. A seven brake H.P. Priestman oil engine is used to drive a Victoria dynamo.

JOHNSTONE'S ELECTRIC CONDUITS.—We have received from the International Electric Subway Company (Limited) a copy of a pamphlet giving flattering testimonials to the value of the Johnstone system of electric conduits owned by that Company. The testimonials are chiefly from America, where the Johnstone system has been in use for some years, and where considerable satisfaction is expressed at the results obtained. This system was described in our issue of February 19th last.

THE MIDLAND ELECTRICITY COMPANY.—This firm will in future devote themselves exclusively to the development of the engineering and construction branch of their business.

HOTEL LIGHTING, &c.—The Great Northern Railway Company have recently purchased the Victoria Hotel, Bradford; and Messrs. Marsh, Jones and Cribb, of Leeds, who have the decoration and refurnishing in hand, have sublet the contract for the bell work and electric light to Messrs. Woodhouse and Rawson United, Limited. The current required is to be obtained from the Bradford Corporation Station.

LIGHTING OF OMNIBUSES.—The Lithanode and General Electric Company, working in conjunction with Messrs. Willing, have introduced a combined battery and electric lamp, which after three months' practical test is to be provided for the electric lighting of a complete line of road car omnibuses, superseding the oil or compressed gas hitherto used. The battery has five cells, and weighs about 15lb.

MR. R. G. IVEY.—Mr. Ivey has secured the contract for the electric lighting of Devonshire House, Bishopsgate-street, E.C., and also for the lighting of several business houses in Fenchurch-street.

COMPANIES' MEETINGS & REPORTS.

Reuter's Telegram Company (Limited).

The twenty-eighth ordinary general meeting of the shareholders of this Company was held on Wednesday, at the offices, 24, Old Jewry, "for the reception of a report and balance-sheet from the Directors, the declaration of a dividend, and the election of a director and auditors." Admiral the Right Hon. Sir J. C. D. Hay, Bart., K.C.B., presided.

The SECRETARY (Mr. Walter F. Bradshaw) having read the notice convening the meeting,

The CHAIRMAN said: I have now to move the adoption of the report. Before, however, making a few remarks on the operations of the Company during the past year, I think a few words of explanation are due to shareholders in reference to the delay which has occurred in holding the annual meeting. The 1st June is the regular date fixed by the Articles of Association, but in former years it has been found possible to complete the accounts by the end of April. This year, however, owing to the greater scope of our business, and the more complicated accounts we have to deal with, we have been obliged to revert to the original practice of holding the annual meeting at this period; and it may be a good opportunity to state, that in all probability, we shall not be able to submit the accounts at an earlier date in future. Turning to the profit and loss account, you will find that the revenue from the telegraphic business shows no retrogression. On the other hand, there has been a large increase of expenditure for telegrams and agencies. This increase occurred chiefly during the first half of 1891, when events of exceptional importance were happening in distant quarters of the globe, chiefly North and South America. The second half of the year has shown a very material improvement, which has been maintained up to the present time. In the opinion of the Directors, the results for the past year are satisfactory, taking into account all the exceptional circumstances with which the Company has had to contend. Without venturing to prophesy, we have good reason to hope that we shall this year earn a fair dividend and be able to strengthen the reserve fund, which I may remark, for the information of new shareholders, was primarily built up to equalise the dividend. The extraordinary, and I may add, not recurring expenditure, referred to in the

Digitized by Google

report, comprises chiefly alterations to the premises, 24, Old Jewry, necessitated by the increased staff we have to employ, and also by the telephonic service between London and Paris. This service has involved important structural rearrangements, chiefly in order to secure a room impervious to outside sounds, as only the most expert telephonists are able to catch the sound of the voice coming over such a long distance. I may mention incidentally that 8,000 words were heard by our telephonists, and recorded within three quarters of an hour. The lease of No. 25, Old Jewry has been acquired for our advertisement business, which may be said to be still in its infancy. The legal formalities which had to be gone through before we could commence operations were only completed about the middle of last year, and since then, as you are aware, there has been considerable financial depression, which reacts immediately on advertising. We have not taken credit in the profit and loss account for any profit made under this head last year, but have applied it in reduction of the preliminary outlay incurred for the organisation of the new branch. We have every confidence that with a revival of financial and commercial activity advertising will prove a lucrative source of income to the Company. With these few words I now move the adoption of the report (in which a dividend of 5 per cent. was declared, free of income tax).

Baron GEORGE DE REUTER: I have much pleasure in seconding the motion.

The resolution was carried unanimously.

The Hon. MARK F. NAPIER afterwards proposed the re-election as a Director of Baron George de Reuter.

The CHAIRMAN seconded the resolution, which was carried unanimously.

On the motion of Mr. LOVEDAY, seconded by Mr. JOSEPH MOORE, Messrs. Welton, Jones, and Co. were re-elected auditors to the Company.

Mr. LOVEDAY then proposed a vote of thanks to the Chairman, Directors, and officials.

Mr. MOORE seconded the motion, which was unanimously adopted.

The CHAIRMAN: Gentlemen, on behalf of my colleagues and myself, I have to thank you very much for the vote of confidence you have been pleased to pass, and to assure you that we trust, now that we are in smoother water, that our duties may be less arduous. Whatever they may be, however, I hope that we shall continue to give you satisfaction, and the business of the Company that attention which it certainly deserves.

The proceedings then terminated.

The following is the report of the Directors of the Company:—

The Directors report that the net profits for the year ending December 31st last, after payment of current expenses, and deducting rebate on unexpired subscriptions, amount to £1,514. 6s. 10d., including the amount brought forward from the last account. In accordance with the Articles of Association, the Directors have charged extraordinary expenditure for alteration of premises, &c., to the reserve fund, and have transferred £3,000 to profit and loss account. From the amount thereby made available for distribution the Directors declare a dividend of 5 per cent., free of income tax, for the year 1891. This will absorb £4,415. 9s. 6d., and leave a balance of £98. 17s. 4d. to be carried forward. The dividend warrants will be payable on the 4th June. Baron George de Reuter retires from the direction, but offers himself for re-election. Messrs. Welton, Jones and Co. offer themselves for re-election as auditors.

Consolidated Telephone Construction and Maintenance Company (Limited).

The following is the Directors' report to be presented at the eleventh annual general meeting to be held at the Cannon-street Hotel, London, on Thursday next, the 9th inst., at 12 noon:—

The Directors submit to the shareholders the report and accounts of the operations of the Company for the year ended March 31, 1892, showing a net profit of £7,188. 4s. 8d., which, with the amount carried forward from last year, leaves a balance of £8,904. 9s. 6d. for disposal, after making provision for doubtful debts. The Directors propose to deal with the amount available as follows, viz.: to pay a further dividend of £1 per cent. for the half-year on the ordinary shares, and £3 per cent. on the preference shares for the half-year, making, with the interim dividend paid in November last, £6 per cent. for the year on the preference shares and £3. 10s. for the year on the ordinary shares; writing off the sum of £617. 4s. 10d. for depreciation of plant, machinery, and furniture; also £63. 16s. 8d. from cost of new building; thus leaving a balance of £1,366. 7s. 9d. to carry forward.

It is with regret that the Board find the figures for the year are not so satisfactory as on previous occasions. The falling off in the profit in manufacturing is owing to American, French, and German competition, the prices of our manufactures having had to be reduced to meet the demand for cheap goods, while the heavy duties placed on our instruments abroad have no doubt tended to reduce our sales in that direction. Every effort is being made to reduce the expenditure, both in the manufacturing department and in the office expenses. It will be seen that certain items of expenditure are charges on the present occasion, which will not recur.

On the result of the accounts being known, your Directors unanimously resolved to relinquish half of their fees for the year ending March 31, 1892.

Agencies for the sale of your manufactures have been established throughout the United Kingdom. The Company has also an exhibit of its manufactures at the Crystal Palace Electrical Exhibition, which is attracting a considerable amount of attention.

Your Directors are now engaged in organising a private wire telephone rental business. This fresh source of revenue will, they hope, be of a lasting nature.

The subsidiary Companies continue to make progress, as is shown by the following statement:—

	Year ending March 31st.					
	Paying Subs.		Rental.		Increase.	
	1891.	1892.	1891.	1892.	Subs.	Rental
Telephone Co. of Austria	3,263	3,588	£20,500	£22,500	325	£2,000
Anglo-Portuguese Telephone Company	2,074	2,139	£13,458	£13,640	65	£182
Total increase for the year...					390	£2,182

The Austrian Government have signed a contract with the Telephone Company of Austria for the purchase of that Company's exchange business, to take effect from the 1st January, 1893. The result to your Company will be the receipt of a large amount in repayment in respect of the securities we hold in that Company.

In accordance with the Articles of Association, the following Directors retire by rotation, and, being eligible, offer themselves for re-election, viz.: J. H. Buckingham, Esq., and Richard Van Zeller, Esq. The auditors, J. G. Griffiths, Esq., F.C.A. (Messrs. Deloitte, Dever, Griffiths and Co.), and A. E. Green, Esq., F.S.A.A., also retire, and offer themselves for re election.

Elmore's German and Austro-Hungarian Metal Company (Limited).

The Directors of the above Company have just issued their report for the fifteen months ending December 31st last. The report states that the negotiations for the purchase of land, buildings, and water power in Germany were completed on May 4th last year. The property is very valuable for the purposes of the Company. It is situated on the left bank of the River Sieg in Rhenish Prussia, about 40 miles from Cologne. An extensive factory had been partly erected by the previous owner of the property, and the Directors have since completed the building according to the special requirements of the Elmore process, which is capable of an output of from 10 to 20 tons per month. The original property included two turbines and gearing for utilising the water-power up to 550 H.P., which will be sufficient to work the factory up to an output of 80 tons per month. The cost of the whole property (lands, buildings, &c.), has been £22,000, which the report states has been valued by an official German valuer at £43,661, and a further sum of £6,610 has been spent on machinery, &c. Some difficulties have been experienced in obtaining legal possession of the property; and the Directors, therefore, in order to conform to the German law, decided to constitute a new Company (Elmore's Metall Actien-Gesellschaft), particulars of which were given in our issue of May 20th last. The Directors state that work has actually been commenced at the factory, and a delivery of goods has been made. Orders are coming in freely through the agency which has been established at Cologne; and the Directors anticipate that after a few weeks the factory will be fully at work, and have more orders than they can execute. The Directors have taken the necessary steps for working their several patents in Austria-Hungary; and the representative of the Company in Vienna is in negotiation with a firm of metal workers for working the Elmore patents under licence from this Company. With reference to finance, the Directors have thought it desirable in the interests of the Company to take steps with the view of relieving the pressure on its funds caused by the existing debenture stock, feeling that until profits are earned the interest amounting to £3,000 per annum and the liability there exists of repaying the capital sum by instalments during the next five years is a heavy charge upon the working capital. The result of negotiations is a proposal provisionally accepted by the principal holders of the debenture stock, by which the £50,000 of 6 per cent. debenture stock will be redeemed, and replaced by fully paid 7 per cent. preference shares; such shares to be entitled to further dividends *pro rata* after the ordinary shares shall have received dividends of 10 per cent. per annum. In order to enable the Board to accomplish this redemption of debentures, consent will be asked at the general meeting to the issue of preference shares to be exchanged for debentures. At the same time sanction will be asked to the issue of the 25,000 shares of the original issue, at present unallotted, either wholly or in part as preference shares, at the discretion of the Directors as to the time and manner of issue, for the purpose of providing additional working capital as may be required.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 302-322, *&c., &c.*]

ELECTRICAL INSTALLATION COMPANY (LIMITED).—This Company was registered on the 27th ult. with a capital of £1,800, in £1 shares. The objects are to carry on the business of electrical, mechanical, and hydraulic engineers in all their branches; to supply electricity for the purposes of light, heat, motive power, or otherwise; to construct, lay down, establish, fix, and carry out all necessary engines, dynamos, motors, cables, wires, lines, accumulators, lamps, and works; to generate, accumulate, distribute, and supply electricity; and to act as agents for the sale of

Digitized by Google

electrical machinery and apparatus, and for any business connected in any way with electrical engineering. The signatories are:—

	Shares.
J. G. O'Brien, 2, Egerton-mansions, South Kensington	1
Edmond L. O'Brien, 6, South-street, Thurlow-square, S.W., electrical engineer	1
Mrs. J. G. O'Brien, 2, Egerton-mansions	1
Mrs. T. O'Brien, 6, South-street, Thurlow-square	1
Cuthbert E. Heath, Lloyd's, E.C.	1
Evan W. H. Fyers, 96, Eaton-terrace, electrical engineer	599
Capt. H. A. N. Fyers, 19, Onslow-gardens, S.W.	1

The first Directors are John G. O'Brien, Edmond L. O'Brien, and Evan W. H. Fyers, who are also the managers. Registered office: 1, Prince's-mansions, Victoria-street, Westminster, S.W.

VEALE AND CO. (LIMITED).—This Company was registered on May 26th, with a capital of £10,000, in £1 shares, by Crompton and Co. (Limited), Mansion House-buildings, London, E.C. The objects are to enter into and carry into effect, with such modifications (if any) as may be considered necessary, the draft contract already prepared in the name of the above Company, and made with Mr. John E. Veale, of St. Austell, Cornwall, for the acquisition by the Company of the business, machinery, stock and other property of the said Mr. J. E. Veale, and for the purchase by, and the transfer to, the Company of the Board of Trade licence to supply electricity in the Local Board District of St. Austell, Cornwall, and of the electrical installation and agreements in connection therewith, and to carry on the business of electricians, electrical contractors, suppliers of electricity for the purposes of light, heat, motive power or otherwise, and manufacturers of electrical apparatus. The signatories are:—

ABELL'S ELECTRICAL ENGINEERING COMPANY (LIMITED).—An agreement, made the 7th ult., between Thomas K. Abell and William Hughes (the vendors), of the one part, and the above Company of the other part, determined that the Company should acquire the business of electrical engineers, colliery furnishers, and machinists which had for some time past been carried on by the vendors under the style of "Abell and Hughes," at the Steam Factory, Raglan-street, St. Helen's, Lancashire, and that the consideration for the said sale should be the sum of £650, to be satisfied as follows:—£50 in cash to Thomas K. Abell; £325 by the allotment to the said Thomas K. Abell of 65 fully paid-up shares of £5 each; and £275 by the allotment to William Hughes of 55 fully-paid shares of £5 each. The Company was registered on May 3, 1892, with a capital of £5,000, in £5 shares, with objects as stated above.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The annual return of the above-named Company, made up to May 18, 1892, was filed on May 24, 1892. The Company was registered on January 8, 1873, with a capital of £1,300,000, in £10 shares. At the time of making-up, the whole of the shares were taken up, the full amount called, and all calls (£1,300,000) paid.

EDISON GOWER-BELL TELEPHONE COMPANY OF EUROPE (LIMITED).—The annual return of the above-named Company, made up to April 14, 1892, was filed on April 19th following. The Company was registered on October 28, 1881, with a capital of £500,000, in £1 shares, to carry on the business of a telephone, telegraph, and electric light, heat, and power supply company; but the Company is not allowed to manufacture telephones or telephonic apparatus. At the time of making-up 385,009 shares had been taken up, of which 370,000 have been issued as fully paid. Upon the remaining 15,009 shares the full amount had been taken up, and, with the exception of £4, paid. The principal shareholders are the Consolidated Telephone Construction and Maintenance Company (209,994 shares), Theodore Paskas, Joshua F. Bailey, and George E. Gouraud (72,000 jointly), George E. Gouraud (94,996), Theodore Paskas (4,000), and Joshua F. Bailey (4,000).

ELECTRICITY SUPPLY CORPORATION (LIMITED).—An agreement made May 19, 1892, between the above-named Corporation of the one part and Agostino Gatti and Stefano Gatti of the other part, states that by a former agreement made May 18, 1892, between the same parties, it was determined that the Corporation should issue, and Messrs. Gatti should accept, such a number of ordinary shares in the Corporation as together with the shares already issued would make up the nominal amount of £50,000, and that the amount payable upon such shares should be retained by Messrs. Gatti on account of the indebtedness of the Corporation to them. At the time of the said agreement 359 shares of the nominal value of £10 each had been taken up, and therefore the number of shares required to make up the said nominal amount of £50,000 is 9,282 shares of £5 each. Messrs. Gatti have expended amounts far exceeding the £46,410, on behalf of the Corporation, and therefore the present agreement determines that the Corporation shall allot the said 9,282 shares to Messrs. Gatti or their nominees, numbered 719 to 10,000 inclusive, and that the sum of £46,410 payable in respect of such shares shall be retained by Messrs. Gatti on account of the indebtedness of the Corporation.

ELIESON ELECTRIC COMPANY (LIMITED).—This Company, which was registered on June 24, 1887, with a capital of £600,000, in £5 shares, has been dissolved. The last return, made up to December 31, 1890, and filed on May 21, 1891, showed that 31,185 shares were taken up, all of which were issued as fully paid.

ELMORE'S FRENCH PATENT COPPER DEPOSITING COMPANY (LIMITED).—The annual return of this Company, made up to the 6th ult., was filed on the 18th. At the time of making up, all the shares had been taken up, and the 33,250 shares had been issued as fully paid in part payment of the purchase consideration. Upon the remainder the full amount had been called, resulting in the payment of £133,015. 6s., and leaving £484. 14s. in arrears, while £8 had been paid on 13 shares forfeited.

ISLINGTON AND GENERAL ELECTRIC SUPPLY (LIMITED).—The capital of the above-named Company has been raised from £800 in £5 shares to £250,000, by the creation of 49,820 shares of £5 each (filed May 21, 1892). *See* full prospectus in our last issue.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 16th, was filed on the 20th. The Company was registered on March 4, 1878, with a capital of £400,000 in £10 shares. At the time of making-up, 37,548 shares had been taken up, on each of which the full amount had been called, and all calls have been paid, while £8,000 has been paid on 800 shares forfeited.

MANLOVE, ALLIOTT AND CO. (LIMITED).—The annual return of the above-named Company, made up to April 9, 1892, has been filed.

MATHER AND PLATT (LIMITED).—An agreement made May 14, 1892, between William Mather and John Platt (the vendors) and the above Company states that the vendors have for some time past carried on the business of engineers at the Salford Iron Works, Manchester, and that the Company has been duly registered with the object, among others, of taking over and carrying on the said business. The present agreement, therefore, determines that the Company purchase (1) the goodwill of the said business, with the exclusive right of using the title of "Mather and Platt," and of representing that the Company is carrying on their business in direct continuation to that firm, together with the benefit of all existing patents, patent rights, licences, trade marks, and brands belonging to the firm of Mather and Platt; (2) all the lands, works, buildings, &c., and all fixtures; (3) all the plant, loose machinery, tools, utensils, stock-in-trade, book debts, chattels, and effects; and (4) all other property to which the firm of Mather and Platt may be entitled. The consideration for the said sale is £272,155. 17s. 4d., satisfied as follows:—£100,000 by the issue of 1,000 debentures of the Company for £100 each (to be a first charge on the entire assets of the Company, including its uncalled capital for the time being), carrying interest at £5 per cent. per annum, the principal to be repayable on January 1, 1902, with power for the Company to redeem part or all such debentures at £105 per cent. at any time after a notice of six months; £135,000 by the allotment of 15,000 shares in the Company, upon each of which the sum of £9 is to be credited as having been paid up, and by the payment of the balance (£37,155. 17s. 4d.) in cash. The purchase is to be considered as having been made on and to take effect as from January 1, 1892, and was, at the time of the signing of the agreement, about to be completed on June 1, 1892, when the Company was to pay the said £37,155. 17s. 4d. in cash to the vendors, or as they directed. The second schedule to the above mentioned agreement details the purchase consideration as £41,991. 5s. 8d. for the trade debts and trade contracts, and £41,449. 12s. 11d. for the patents and goodwill.

MISCELLANEOUS.—CYNON (ABERDARE) TIN PLATE COMPANY (LIMITED), tin plate manufacturers, mechanical and electrical engineers, &c.; capital £15,000, in £100 shares.——JOHNSON'S PATENTS (LIMITED), mechanical and electrical engineers, &c.; capital £40,000, in £10 shares.——SCOTTS, ENGINEERS (LIMITED); capital £20,000, in £1 shares.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend of 3s. per share, free of income-tax, for the quarter ended March 31st last, and payable on the 24th inst. The transfer books of the Company will be closed from the 17th to the 23rd inst., both days inclusive.

CAMBRIDGE ELECTRIC SUPPLY COMPANY (LIMITED).—The prospectus of this Company has just been issued. It has been formed for the purpose of taking over from Messrs. C. A. Parsons and Co. the powers granted by the Provisional Order obtained by the Corporation, enabling them to supply the electric current within the borough. The capital is £50,000, in £10 shares, payable, £2 on application, £2 on allotment, and the balance (up to £8) by instalments of £2 at intervals of not less than one month. It is expected that current will be turned on in October next, and the prospectus states that the results of canvasses made satisfies the Directors that they will commence operations with a good prospect of success. The Directors include Sir B. C. Browne, D.C.L., and Mr. J. B. Simpson, Directors of the Newcastle and District Electric Lighting Company (Limited); and the Hon. C. A. Parsons, the managing director, is also managing director of the last-named Company.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended May 29th were £713, as against £768 for the corresponding period of last year, being a decrease of £55. The total receipts to date, from January 1st last, amount to £17,409, against £16,143 in the corresponding period of 1891, being an increase of £1,266.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of May were £3,600, as compared with £3,633 in the corresponding month of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the month of May amounted to £54,842, against £53,829 in the corresponding period of 1891, being an increase of £1,013.

Digitized by Google

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of May amounted to £40,612, and to £37,064 in the corresponding period of last year, a decrease of £3,548.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—It is announced in our advertisement columns that the transfer books and register of members were closed on the 25th ult., and will remain closed until the 7th inst. inclusive.

INDIA-RUBBER, GUTTA-PERCHA, AND TELEGRAPH WORKS COMPANY (LIMITED).—Application has been made to the Stock Exchange to grant a special settling day in and to grant a quotation to the further issue of 8,400 shares, Nos. 41,601 to 50,000.

NEW YORK BELTING AND PACKING COMPANY (LIMITED).—At the first ordinary general meeting of this Company, held at the Cannon-street Hotel on Saturday, the Chairman (Mr. Samuel Pope, Q.C.), said that the business was, in the judgment of the Directors, healthy, and likely to be prosperous. Dividends of 10 per cent. on the ordinary, and 8 per cent. on the preference shares, were declared.

ORE DRESSING AND GOLD EXTRACTION COMPANY (LIMITED).—The fifth ordinary general meeting of the shareholders in this Company, formed for the purpose of amalgamating the working of the two processes for ore dressing and gold extraction—the Newbery-Vautin and the Lubrig—was held on Tuesday, at Winchester House, Old Broad-street, under the presidency of Mr. F. Thorne, when the report and accounts were adopted.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended May 27, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,449.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 734.—Vol. XXIX. FRIDAY, JUNE 10, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The subject of nomenclature attracts attention at every Electrical Congress, and, in view of the approaching Exhibition at Chicago, M. Hospitalier, who has always shown exceptional interest in this matter, has recently expressed some opinions which will meet with general approval. It will be seen from the printed account, published in another column, that M. Hospitalier advises that the introduction of new names should be avoided wherever simple compound words can be found the meaning of which is self-explanatory. In this opinion we quite concur. The names of Joule and Coulomb are not commonly used to express the units of electrical energy and quantity, in spite of the advocacy of scientific men. The far more expressive names of watt-hour and ampere-hour have been found the fittest to survive. In the naming of new units this example should be borne in mind. It is impossible to honour all first-class electricians in the graceful manner originated by the British Association. The fundamental units had, of course, to be named in some arbitrary fashion, and the method adopted was the best that could have been chosen. A derived unit should, however, show its meaning by the way in which its name is built up, wherever this can be done without forming a compound word which is either too long or too difficult to pronounce.

The sentiments expressed by the promoters of the modified form of copper "corner," which is to commence its beneficent operations on July 1st, are in every way admirable. There is no intention, we are told, of unduly putting up prices, and trade is to be in no way inconvenienced; what is aimed at is merely a stoppage of the too keen competition which has obtained of late among copper producers. We seem to have a dim recollection of having heard this tale before. The difference between £45. 10s. per ton, the average price for the past five months, and, say, £60 may possibly be thought by no means an *undue* elevation; nevertheless, it is to be remembered that every one of the 3,480 pennies will have to come out of the copper consumer's pocket. However, the excellent intentions of the promoters of the scheme, supplemented by reminiscences of the fate which befell the 1888-89 corner, will tend to moderation.

The carbon submarine cable relay devised by Mr. Charles Cuttriss, of the Commercial Cable Company, a description of which will be found in this issue, is a very ingenious arrangement, which will no doubt answer within the limits mentioned. Dr. Alexander Muirhead and Mr. H. A. C. Saunders, of the Eastern Telegraph Company, were working in this direction more than ten years ago, and took out a patent covering the use of the variable resistance of selenium cells for attaining their object; but they could not get these cells to answer. We may mention that Allen and Brown's relay, to which reference is made by Mr. Cuttriss, has worked at the rate of 28 words per minute with the Saunders curb key through 620 miles of cable with the current sent by 14 volts, while with a recorder form of coil it would do much more.

When electric motors really come into use in this country otherwise than as rival attractions to frying-pans at Electrical Exhibitions, the question of the most useful size for certain work will be very important. Machine tools, lathes, drills, &c., may be run by separate motors as at the Elwell-Parker works at Wolverhampton; and a loom may be worked in a similar manner, as has been done by Mr. Livesey at Blackburn; with greater economy than the driving of each line of shafting in a factory by a large motor. But in cotton spinning a high speed is used at the spindles, and with ball bearings it is said that 16,000 revolutions per minute may be reached. Such speeds as this are admirably suited for electrical transmission, but the first cost of a small motor for each spindle would be prohibitive, even if long multiple field magnets were arranged to take a number of armatures. The power used in spinning varies from one-thirtieth to one-five-hundredth of a horse-power per spindle; and as rather more than a thousand spindles go to a mule in modern work, there is ample choice for the electrical engineer between one motor for each mule, or smaller ones at higher speeds mounted on the carriages and driving the tin rollers direct. It is probable that fully one-third, if not one-half, of the power is spent at present upon friction of shafting, &c., and nearly all this might be saved by applying small motors direct to the work.

Whether the public has become accustomed to delays or whether things are really going more smoothly we do not know; but, at any rate, comparatively little is now heard about breakdowns on the City and South London Railway. As in all cases where authentic information is not forthcoming, the quidnunc has been at work. The locomotives supplied by one firm we are told are electrically weak, while those supplied

Digitized by Google

by another are mechanically defective, and so on. There are always good reasons for reticence in these matters. Those responsible for the working of a new concern like the City and South London line naturally do not care to parade its failings too prominently. Contractors and designers of machinery dislike what they consider to be the captious comments of arm-chair engineers, and are moreover disinclined to place gratuitously at the disposal of their trade rivals practical knowledge which it has cost much to attain. Nevertheless, it is impossible not to regret in the interests of the electric traction industry at large that there should be so much mystery about so simple a problem, and so much sensitiveness in regard to honest and competent criticisms.

It would be in the highest degree detrimental if the mishaps which have occurred South of the Thames were repeated on the northern bank; an untoward consummation which a plain straightforward engineering account of the first year's working of the line, such as was recently given to the Institution of Electrical Engineers in connection with the electric lighting of Newcastle, would go a long way to obviate. A perfect "loco" motor no more than anything else of the kind springs straight from the designer's brain. That the City and South London Railway is, on the whole, a distinct electrical success is amply proved by the evidence before the recent Select Committee. Not one of the many opponents to the new schemes ventured to deny it.

The report upon the proposed Mechanical Sciences Tripos at Cambridge, of which we print an abstract this week, has to be discussed in the "Arts School," and a "grace" giving effect to the recommendation will then be offered to the Senate, and, if approved, the Tripos will be established. The discussion will not take place until Michaelmas Term next. We hope to comment on this important departure on an early occasion.

Electric Traction in France. — The Marseilles-St. Louis trolley line came into regular operation on the 22nd ult.

Royal Society Conversazione.—The second *conversazione* of the Royal Society will be held on Wednesday, June 15th.

Telegraphs Bill.—This Bill was read a second time in the House of Commons on Friday last, and referred to a Select Committee.

The New Telephone Company's Bill.—The order for the second reading of this Bill was discharged and the Bill withdrawn last Thursday.

H.M.S. "Royal Sovereign."—There are no less than 800 electric lights and 30 miles of electric wire on board this latest addition to our fleet of battle-ships.

Armoured Cables.—According to *L'Electricien*, Siemens and Halske's German patent for electric light cables sheathed with iron strip has been declared invalid.

Interurban Telephony.—On Friday last the Director-General of Posts and Telegraphs opened the telephone lines between Paris and Antwerp, and Rheims and Charleville.

Institution of Electrical Engineers' Conversazione.—The *conversazione* of the Institution of Electrical Engineers will be held on Friday, July 1st, in the galleries of the Royal Institute of Painters in Water Colours.

The Salomons Scholarship.—Mr. C. H. C. Woodhouse, Second Year Matriculated Student Electrical Engineering Department City and Guilds Central Institution, Associate Royal College of Science, B.Sc. London University, has been awarded the Salomons Scholarship, value £35.

Lightning.—A Reuter's telegram from Vienna states that great destruction was caused by a violent thunderstorm which passed over the Alpine districts of Lower Austria on Saturday evening last. According to a despatch from Gratz, an isolated cottage at a place called Gamin, near Thormauern, was struck, and its eight occupants killed. The cottage was set on fire by the lightning.

St. Pancras Vestry Electricity Supply.—A paragraph has been going the round of the papers to the effect that the St. Pancras Vestry is supplying current at the abnormally low price of 3d. per Board of Trade unit. Some qualification of this statement is, however, needed. The Vestry supply current either for lighting or motive power *during the day* at 3d., but the price of the night supply is 6d.

The Société Française du Télégraphe de Paris à New York.—The shareholders of the Société Française du Télégraphe de Paris à New York, between whom and the Board of that concern there is a coolness, recently held their annual general meeting without a single member of the Board being present. The *Bulletin International de l'Electricité* remarks that it is not stated whether the shareholders voted themselves a dividend.

The Paris-Bordeaux Telephone Trunk Wire.—*La Lumière Electrique* gives some interesting particulars with regard to the cost of this line of 360 miles, which came into operation on Wednesday. The total cost of the line has been £26,000, which will be repaid by the State out of the profits accruing. The Bordeaux Chamber of Commerce subscribed £16,800, and that of Paris £5,200; to this sum £4,000 was added by the Bordeaux Municipality.

An Extraordinary Accident.—A Reuter's telegram dated New York, May 28, is responsible for the following:—An extraordinary accident occurred to-day at the Edgar Thompson steelworks at Braddock, Pennsylvania. A number of men were working on a travelling crane in the blacksmiths' shop when the boom came in contact with an electric light wire and cut through the insulation. Instantly the force of the current passed down the iron framework of the crane. All the men at once fell to the ground insensible, and two of them were killed.

Electric Lighting Provisional Orders.—The following Electric Lighting Provisional Orders have been granted by the Board of Trade this Session, and Bills to confirm them have been introduced into Parliament:—Aberystwyth, Ashton-under-Lyne, Dublin, Fareham, Govan, Halifax, Harwich, Kilkenny, Limerick, Liverpool, Maidstone, Newbury, Oxford, Sheffield, Sutton (Surrey), Waterford, West Ham, Woking Electric Supply Company's (Horsell and Chertsey) Order, Southwark, Wandsworth, Hampstead, Lambeth, Shoreditch, and Whitechapel. In all 24 orders have been granted, as against 58 last year.

Electric Lighting at Cable Stations.—The large station of the Commercial Cable Company at Waterville, County Kerry, has recently been lighted throughout with electric light under the supervision of Mr. J. A. McMullen. Coal being expensive and difficult to obtain in the neighbourhood, a 9 H.P. Priestman petroleum engine has been used with great success. Eighty 16 c.p. lamps have been fitted in the offices and the dwelling quarters of the staff. The dynamo and engine are supplemented by a battery of E.P.S. cells. The Canso (Nova Scotia) station of this Company has been lighted for the past year by electricity, which is a great boon to the staff. The lighted station also serves as a landmark for coasting vessels at night.

The Purification of Sulphuric Acid for Accumulators.—As will be seen by Dr. Kugel's article in another column, metallic impurities in the electrolyte are considered by him to play a very important part in diminishing the capacity of secondary cells. Now these deleterious metals are completely precipitated in a dilute sulphuric solution by sulphuretted hydrogen; and Dr. Kugel utilises this fact to purify acid intended for accumu-

Digitized by Google

lators. A current of the gas is passed through the electrolyte, which is then filtered after four-and-twenty hours' rest. When this process of purification is carried out alone it is preferable to generate the sulphuretted hydrogen within the acid itself, by treating it with baric sulphide. This method has been employed by Herr Lucas at Hagen.

Exeter.—At Wednesday's meeting of the City Council the lighting of the city came up for discussion. Communications from the Gas Company stated they were prepared, under a seven years' contract, to supply improved lamps at cost price, and provide gas at 2s. 9d. per thousand cubic feet, and for large special lamps in the open spaces at 2s. 6d. per thousand. A memorial signed by about one hundred ratepayers in the principal streets asked that electric light might now be provided. Alderman Willey considered the question required further looking into, and moved that the correspondence be referred to the Lighting Committee, who should be asked to report on the relative cost of the two systems. This was agreed to after some discussion.

The St. Clair Tunnel.—"Great trouble," says *Engineering*, "is being experienced in ventilating the St. Clair Tunnel, which passes under the Detroit River, and is one of the principal connecting links between the railway systems of the United States and Canada. The ventilation is said to be so bad that difficulty is found in obtaining drivers willing to run the engines through it. Owing to the steep grades, very heavy engines are used for working the tunnel section, and these engines turn out large quantities of smoke and products of combustion. Smoke consumers are to be fitted to the engines with a view of mitigating the nuisance. The tunnel was opened only last year." This would seem to afford another opportunity for the Edison-Thomson-Houston Company to advertise the capabilities of large electric locomotives.

Niagara and Electricity.—Under this heading Prof. George Forbes contributed a column-long letter to *The Times* of Wednesday, describing the operations of the Cataract Construction Company, an illustrated account of which appeared in *The Electrician* of December 5, 1890 (Vol. XXVI., page 144). The intake canal, 1,500ft. long, at right angles to the river, has been cut. The vertical shaft, 140ft. deep, is being sunk, and from the lower level the tunnel, 28ft. high and 18ft. wide and 6,700ft. long, has been carried at a slope of 7 per 1,000, to issue at the foot of the cliffs below the falls, just under the suspension bridge. This work is all nearly completed. The lining of the tunnel with four courses of bricks is going on at the rate of 100,000 a day, and this rate is about to be increased. The turbines are in hand. Part of the power is to be used in factories now being built directly over shafts.

The Patent Office.—According to the ninth report of the Comptroller-General of Patents recently presented to Parliament, 22,888 applications for patents were made last year, against 21,307 in 1890, and 17,110 in 1884. The figures for 1891 show an increase of 7½ per cent. over those for 1890. The total income of the Patent Office from all sources during 1891 amounted to £203,520, of which £181,777, or 89 per cent., accrued from patent fees. The total expenditure during 1891, including £21,703 devoted to new buildings, amounted to £103,180, leaving a surplus of £100,339. Out of the total expenditure £54,267, or nearly 53 per cent., went in salaries and wages to the Patent Office staff. The number of readers at the Patent Office library during the year amounted to nearly 100,000. The total number of registered patent agents is now 236, five names having been added during 1891.

Personal.—Mr. W. B. Esson has resigned the position of manager and electrician to Messrs. Paterson and Cooper, which he has held for nearly nine years.—Mr. E. H. Taylor has been appointed sole agent for Brazil of the Brush Electrical Engineering Company.—Mr. Douglas Wells, superintendent of telegraphs, and engineer to the Colony of the Bahamas, also consulting engineer and electrician to the Colonial Government, has resigned these positions. Mr. Wells, who we may mention laid the Bahamas-Florida cable between Nassau and Jupiter, successfully established the system of working direct to Jacksonville, Florida, through 211 knots of cable and 405 miles of land line, using the American closed-circuit system with great success, a speed of 35 words a minute being obtained between the two places. There are seven small stations between Jupiter and Jacksonville. With the exception of the Havana cable this is the only submarine cable working on closed-circuit system using sounders.—Mr. Percy Still has been appointed resident engineer to the Chelsea Electricity Supply Company.

Greenwich Observatory.—On Saturday last the annual visitation of the Board of Visitors took place at the Royal Observatory. The Astronomer Royal stated in his report that the Admiralty had authorised the erection of the south wing of the proposed Physical Observatory during the present financial year. During the year ending 1892, May 10th, photographs of the sun were taken on 219 days. The solar activity had increased, it was stated, in a remarkable manner during the past year. The question of the association of magnetic disturbances with sun spots was of great interest. It appeared from the Greenwich records since 1873 that most of the magnetic storms occurred when an exceptionally large spot was visible on the sun near the centre of the disc, or about the time of some great change in a sun spot; also that magnetic storms were generally characterised by a sudden initial movement of the magnets, simultaneous in all parts of the earth. In connection with the magnetic department, attention was drawn to the fact that the passage of trains on the electric railway 4½ miles from the Observatory seriously disturbed the instruments.

The McKinley Tariff and Submarine Cables.—We are confident (says a New York paper) that a recent importation of dutiable merchandise at Jupiter, Fla., has not escaped the vigilant eye of Assistant-Secretary Spaulding, who writes the decisions in which the Treasury Department interprets and applies the provisions of the McKinley tariff. We refer to the landing at Jupiter of the American end of the new telegraph cable from Nassau. The law with respect to imported goods of this kind has already been interpreted and applied by Mr. Spaulding. As soon as the American end of the telephone cable from the Canadian town of Windsor emerged from the water at Detroit a few months ago, the watchful Assistant Secretary promulgated a decision that it was clearly dutiable and must be taxed under the law of McKinley. The decision has been published by the department, and, so far as we know, has never been reversed. The American end of the Nassau cable was landed at Jupiter on Saturday last, and the British steamer "Westmeath," after doing the work, slipped away in the darkness of the following night. The protruding end of this cable should be appraised at once, and the full duty should be exacted.

Copper.—We are authorised to state, says the *Statist*, that an understanding has now been arrived at between the American and European producers of copper in regard to the production of the metal for the twelve months from July 1st next. With regard to the above, says our contemporary, we believe that the arrangement is to the effect that the European Companies are to reduce their output by 5 per cent., and that the American Companies are to restrict their exports to Europe. What is aimed at, it will be seen, is a moderate reduction in the production; or rather, perhaps, it would be more correctly described as a stoppage of the too keen competition between producers which has been going on lately, and a reasonable attempt to regulate supply to demand. We understand that there is no intention to put up prices unduly, or in any way to inconvenience the trade. There is to be a committee elected to carry out the arrangement. Each of the Companies will, of course, raise their selling prices, but they will raise them moderately. Two years ago the visible supply was, approximately, 82,000 tons; it is now down to below 54,000 tons. The average prices for the calendar years 1889, 1890, and 1891 for Chilian bars were, respectively, £49. 10s. 6d., £54. 5s., and £52. 9s. 8d. The approximate average price for the past five months has been about £45. 10s.

A Proposed London County Council Electric Railway.—A proposal for the construction of an electric railway to be paid for on the betterment principle has been put on the County Council programme by Mr. Saunders for discussion at an early date. Not long ago the Chairman of the Great Eastern Rail-

Digitized by Google

way said that a fare of twopence for a journey from Enfield to Liverpool-street and back remunerated his Company if there were 500 passengers in the train. This being so, Mr. Saunders concludes that on the electric railway line, the interest on the cost of which would be paid by the improved value of the land, a penny fare for twenty miles would pay, seeing that electric trains are smaller and cheaper than the trains run by the Great Eastern Company. His motion, therefore, will be—"That the Council do instruct an experienced railway engineer to advise it as to the best route for an electric railway, passing underground through Whitechapel, rising to the surface at suitable points, and extending about 20 miles north and south from the centre of the railway at Whitechapel; this advice to be obtained with a view to preparing plans and estimates and submitting to Parliament a scheme for the construction of such a line. The cost to be paid by the application of the betterment principle to the increased value of land imparted by the railway. Workmen's trains to be provided at a net charge not exceeding sixpence per week for travelling ten miles daily and return."

Conference of Telegraph Clerks.—The annual conference of the Postal Telegraph Clerks' Association was opened on Saturday, at the Cannon-street Hotel; Mr. A. W. North, of the Central Telegraph Office, presiding. The attendance at the conference was the largest on record. After prolonged discussion, the following resolution was passed:—"That this conference respectfully calls upon the Postmaster-General to remove the existing restrictions upon the political and civil rights of the officers of this service, and especially calls upon him to grant the right to hold meetings for the discussion of questions of interest to the staff without departmental interference." A resolution dealing with the scale of salaries and in favour of the abolition of classification was carried unanimously. It was then moved:—"That, having regard to the rapid increase of female labour throughout the Service, it is in the opinion of this conference most essential that a limit should be placed upon such labour." But a motion that it was inexpedient to discuss the question of female labour was ultimately put and carried by a large majority. Resolutions relating to errors in telegrams, sick pay, and the "Raikes" scheme were also carried. A resolution was also adopted to the effect that it was advisable that a greater proportion of postmasterships should be given to members of the Telegraphic Service. Cardiff was chosen as the place of meeting next year.

The Chicago Exhibition Incandescent Lighting Contract.—We are informed by the Westinghouse Electric Company (Limited), of 32, Victoria-street, that they have received a communication from the Vice-President and General Manager of the Westinghouse Electric and Manufacturing Company of Pittsburgh, Pa., U.S.A., to the effect that that Company has been awarded the contract for the incandescent lighting of the Chicago Exhibition after severe competition. The contract covers apparatus to the extent of about 90,000 16-c.p. lamps. According to the *Western Electrician* of May 28th, the contract price is $399,000, which works out at under $4\frac{1}{2}$ per lamp, as against the last Edison-Thomson-Houston figure of $5.95 per lamp. The first bid was at the rate of $18 50 per lamp. "It cannot be asserted, however," says our Chicago contemporary, "that the action of the committee is entirely conclusive; for if anything has been developed in the strenuous contest of the last eight weeks, it is the fact that the result is never certain until the contract has been actually signed. . . . The competition for the contract has been very keen, not to say bitter, and the contest will become a memorable one in an industry noted for active business rivalries. Neither side can boast that its procedure has been above criticism, and there is not a little, taking the conduct of the negotiations from first to last, that the electrical fraternity will look back upon with regret, and which will not add to the reputation of the industry before the people." The actual signing of the contract depends on the condition that Mr. Westinghouse shall, on or before to-day, June 10th, execute a bond in the sum of $1,000,000 that he will faithfully carry out the provisions of the contract.

Institution of Civil Engineers.—At the annual general meeting of this Institution on Tuesday, May 31st, it was stated in the report of the Council that the additions to the register together amounted to 366; and after deducting 145 names from deaths, resignations and erasures, there was a net increase of 221, bringing up the total number on the register to 5,371, as against 5,150 at the corresponding date last year. This enumeration was irrespective of students. During the financial year ending March 31, 1892, the total receipts amounted to £26,188. The Council awarded a George Stephenson Medal and a Telford Premium to Mr. Alex. R. Binnie; Telford Medals and Telford Premiums to Mr. A. P. Trotter and Mr. W. T. Douglass; and Telford Premiums to Messrs. H. Alfred Roechling, A. H. Curtis, W. Airy, H. Gill, and Prof. W. C. Roberts-Austen. In respect of communications received and not discussed, Telford Medals and Telford Premiums were adjudged to Messrs. F. Fox and Alfred W. Szlumper; and Telford Premiums to Mr. Sheibner, Profs. T. H. Beare and W. C. Unwin, and Messrs. E. Penny, A. D. Stewart, R. H. B. Downes, and W. Matthews. The Howard Quinquennial Prize was awarded to Sir Isaac Lowthian Bell, F.R.S., for his treatise on "The Principles involved in the Manufacture of Iron and Steel." A Miller Prize was awarded to Mr. C. H. Wordingham, Stud.Inst.C.E., for his Paper on "Meters for recording the Consumption of Electrical Energy." The following is the Council for the ensuing year:—President: Mr. Harrison Hayter. Vice-Presidents: Mr. Alfred Giles, M.P., Sir Robert Rawlinson, Sir Benjamin Baker, F.R.S., and Sir James N. Douglass, F.R.S. Members of Council: Dr. W. Anderson, F.R.S., Messrs. J. Wolfe Barry, Alex. R. Binnie, E. A. Cowper, Sir Douglas Fox, Messrs. J. C. Hawkshaw, Charles Hawksley, Sir Bradford Leslie, Messrs. George Fosbery Lyster, James Mansergh, Sir Guildford L. Molesworth, Mr. W. H. Preece, F.R.S., Sir E. J. Reed, F.R.S., M.P., Messrs. William Shelford and Francis W. Webb.

The Scientific Spirit—Old and New.—The following appeared in *Industries* of June 3rd, the writer veiling his identity under the initials "W. M. M.":—

"About 200 years ago a young man, whose name is still held of some account, was engaged in the work of verifying by calculation a theory of his own respecting the curve of the moon's motion in its orbit. There was a discrepancy of 14 or 15 per cent. between the observed and calculated results, and consequently he laid aside at that time any further consideration of the matter. On Friday last the members of the Physical Society assembled in force to hear another young man, whose name is now held of some account, give a statement of the evidence for and against the theory that the earth carries the ether with it in its motion round the sun. The lecture was illustrated with many diagrams of experiments, mostly negative or inconclusive in their results. *Inter alia* there was a diagram of observed and calculated results, showing a discrepancy of about 99 per cent. But science has advanced since Newton's time, and the last thing any modern scientific man would think of doing is to 'lay aside all further thought of this matter' on account of a trifling discrepancy of this sort. There is a good deal to be said for this modern view. Newton was right after all, and a too scrupulous delicacy might have caused him to miss his greatest discovery and the *kudos* attached to it. Adams first calculated the position of Neptune, but Le Verrier published first; and your modern man does not mean to be caught napping so, even if he has to publish before finishing his calculation. Does not Mayer share with Joule in the opinion of half the world the credit of the theory of the conservation of energy, and who would have heard of him if he had stopped to verify? We are even told that it is little short of a crime to 'hide the light that is in us,' no matter how feeble and flickering it may be, lest haply some one greater should waste his strength collecting and arranging the uncompleted work, as Maxwell did for Cavendish. And yet—and yet—the *Principia* will endure for all time: will 'Modern Views of Electricity,' with its choice of inconsistent hypotheses, or 'Electro-magnetic Theory,' with its *rational* (!) system of units, its uncouth phraseology, and its petulant contempt for whatever is not brand new, stand such a test? A bigot for classical education, with an insufficient appreciation of Newton's genius, attributes his superiority in part to the fact that he published in Latin. 'You may think any scientific nonsense you please,' says this misguided person, 'and you may write it down readily enough in English; but you can't put it into Latin, nor, easily, into French. If it goes readily into German, it is probably more scientific and worse nonsense than usual.' But that, of course, is absurd. In these days it is often almost as good a deed to kill a false hypothesis as to establish a true one; and for this purpose the publication of negative results is most useful, nor is it contrary to precedent. Kepler gave his failures to the world, but only after he had arrived at the truth; Faraday gives his negative results, but he draws the logical inference from them. In each case we could ill spare the insight obtained into the mind and method of a genius. A reasonable rule might be laid down that only those who succeed are entitled to show where they have failed; but then how meagre would be the reports of our scientific societies!"

ELECTROMAGNETIC THEORY.—XXX.

BY OLIVER HEAVISIDE.

(*Continued from page 87.*)

§ 141. These properties of the space-integrals of scalar products in the divergent series are formally obtainable from the corresponding ones in the circuital series by changing the suffix from 1 to 2; at the same time changing the type from clarendon to roman should the quantity typified be a scalar. Thus, analogous to (262), (263), we have

$$\Sigma \mathbf{C}_2^2 = \Sigma \mathrm{B}_2\mathrm{D}_2 = \Sigma \mathbf{A}_2\mathbf{E}_2 = \ldots \quad . \; . \quad (265)$$

$$\Sigma \mathrm{D}_2^2 = \Sigma \mathbf{C}_2\mathbf{E}_2 = \Sigma \mathrm{B}_2\mathrm{F}_2 = \ldots, \quad . \; . \quad (266)$$

starting from the square of a vector in the first set, and from the square of a scalar in the second. These transformations all rest upon (249); that is, we pass from any form to the next by the exchange of $-\nabla$ and div between the factors. For example,

$$\begin{aligned} \Sigma \mathrm{D}_2^2 &= \Sigma \mathrm{D}_2 \operatorname{div} \mathbf{C}_2, && \text{by definition of } \mathrm{D}_2, \\ &= -\Sigma \mathbf{C}_2 \nabla \mathrm{D}_2, && \text{by integration, using (249),} \\ &= \Sigma \mathbf{C}_2\mathbf{E}_2, && \text{by definition of } \mathbf{E}_2. \end{aligned}$$

Similarly in all the rest. The preceding equations conveniently summarise them.

But it will be observed that there is another way of pairing terms in the divergent series, viz., a vector with a scalar. The corresponding transformations do not work so symmetrically as the previous. For instance,

$$\begin{aligned} \Sigma \mathbf{C}_2\mathrm{D}_2 &= -\Sigma \nabla \mathrm{B}_2.\mathrm{D}_2, && \text{by definition of } \mathbf{C}_2, \\ &= \Sigma \mathrm{B}_2 \nabla \mathrm{D}_2, && \text{by (244),} \\ &= -\Sigma \mathrm{B}_2\mathbf{E}_2, && \text{by definition of } \mathbf{E}_2, \\ &= -\Sigma \operatorname{div}\mathbf{A}_2.\mathbf{E}_2, && \text{by definition of } \mathrm{B}_2, \\ &= \Sigma \mathbf{A}_2 \nabla.\mathbf{E}_2, && \text{by integration.} \quad . \quad (267) \end{aligned}$$

Here the symmetry breaks down. The last transformation depends upon

$$\Sigma (\mathbf{N}\mathfrak{f})\mathfrak{g} = \Sigma (\nabla\mathfrak{f})\mathfrak{g} = \Sigma (\mathfrak{g} \operatorname{div} \mathfrak{f} + \mathfrak{f}_\nabla.\mathfrak{g}), \quad . \; . \quad (268)$$

which is a case of the theorem (147) or (153). Note that in the second form ∇ has to differentiate both $\mathfrak{f}$ and $\mathfrak{g}$, so that the full expression is in the third form. If the surface-integral vanishes at infinity, we have

$$\Sigma \mathfrak{g} \operatorname{div} \mathfrak{f} = -\Sigma \mathfrak{f}\nabla.\mathfrak{g}, \quad . \; . \; . \; . \quad (269)$$

which is the transformation used in getting (267). We have also, by going the other way,

$$\Sigma \mathbf{C}_2\mathrm{D} = \Sigma \mathbf{C}_2 \operatorname{div} \mathbf{C}_2 = -\Sigma \mathbf{C}_2\nabla.\mathbf{C}_2, \quad . \; . \quad (270)$$

by using the same transformation (269). Next take $\mathrm{D}_2\mathbf{E}_2$. Here the vector is the slope of the scalar it is multiplied by, whereas in the former case, the divergence of the vector was the associated scalar. So it now goes quite differently. Thus,

$$\Sigma \mathrm{D}_2\mathbf{E}_2 = -\Sigma \mathrm{D}_2\nabla\mathrm{D}_2 = -\Sigma \nabla\tfrac{1}{2}\mathrm{D}_2^2 = -\Sigma \mathbf{N}\tfrac{1}{2}\mathrm{D}_2^2 \quad . (271)$$

The result is therefore zero, if the surface-integral at infinity vanishes.

§ 142. It usually happens that potentials present themselves in physical mathematics as auxiliary functions introduced to facilitate calculations relating to other quantities. But in the theory of the elastic solid, the potential function presents itself in a very direct and neat manner; besides that, the elastic theory presents excellent illustrations of the above transformations and the general theory of ∇. If the solid be homogeneous and isotropic, there are but two elastic constants, the rigidity n and the coefficient of resistance k to compression or expansion. Let also $m = k + \frac{1}{3}n$, in Thomson and Tait's notation; then the equation of motion is

$$\mathfrak{f} + n\nabla^2\mathfrak{G} + m\nabla \operatorname{div} \mathfrak{G} = \rho\ddot{\mathfrak{G}}, \quad . \; . \; . \quad (272)$$

where $\mathfrak{G}$ is the displacement, and $\mathfrak{f}$ the impressed force per unit volume, whilst ρ is the density. Whatever limitations may need to be put upon the values of m and n in treating of solids as we find them, in speculations relating to ethers they may have any values not making the stored energy negative. Thus m may, as we shall see presently, go down to the negative value $-n$, keeping n positive.

Split $\mathfrak{f}$ into $\mathfrak{f}_1 + \mathfrak{f}_2$, and $\mathfrak{G}$ into $\mathfrak{G}_1 + \mathfrak{G}_2$, where $\mathfrak{f}_1$ and $\mathfrak{G}_1$ are circuital, and the others divergent. Then (272) may be split into two equations, one circuital, the other divergent. Thus, remembering (193),

$$\mathfrak{f}_1 + n\nabla^2\mathfrak{G}_1 = \rho\ddot{\mathfrak{G}}_1, \quad . \; . \; . \; . \; . \; . \; . \; . \quad (273)$$

$$\mathfrak{f}_2 + (n+m)\nabla^2\mathfrak{G}_2 = \rho\ddot{\mathfrak{G}}_2. \quad . \; . \; . \; . \; . \; . \; . \; . \quad (274)$$

In the circuital equation k does not appear, so that the propagation of circuital disturbances depends only upon the rigidity and density; speed, $(n/\rho)^{\frac{1}{2}}$. In the divergent equation both n and k appear, and the speed of disturbances of this class is $\{(n+m)/\rho\}^{\frac{1}{2}}$. In another form, if we take the curl of (272), the divergence goes out, so that the curl of $\mathfrak{G}$, which is twice the rotation, has the curl of $\mathfrak{f}$ for source, and is propagated independently of compressibility.

And if we take the divergence of (272), we see that the divergence of $\mathfrak{G}$, or the expansion, has the divergence of $\mathfrak{f}$ for source, and the rate of its propagation depends upon both rigidity and compressibility. But when $m = 0$, there is but one speed of propagation, and a complete amalgamation of the two kinds of disturbances.

In equilibrium, when equilibrium is possible, the right members of the last three equations vanish, since they represent "rate of acceleration of momentum" (a long-winded expression). We therefore have

$$\mathfrak{f}_1 = -n\nabla^2\mathfrak{G}_1, \quad . \; . \; . \; . \; . \; . \quad (275)$$

$$\mathfrak{f}_2 = -(n+m)\nabla^2\mathfrak{G}_2. \quad . \; . \; . \quad (276)$$

The solutions are visible by inspection. We see that $n\mathfrak{G}_1$ is the potential of $\mathfrak{f}_1$, and $(n+m)\mathfrak{G}_2$ the potential of $\mathfrak{f}_2$. That is, the displacement produced by circuital impressed force is its potential divided by n; and the displacement produced by divergent impressed force is its potential divided by $n+m$; whilst, in the general case, we must split the impressed force into circuital and divergent parts, and then re-unite them in different proportions to obtain the resultant displacement. Symbolically,

$$n\mathfrak{G}_1 = \operatorname{pot} \mathfrak{f}_1, \quad . \; . \; . \; . \; . \quad (277)$$

$$(m+n)\mathfrak{G}_2 = \operatorname{pot} \mathfrak{f}_2, \quad . \; . \; . \; . \; . \quad (278)$$

$$\mathfrak{G} = \frac{\operatorname{pot} \mathfrak{f}_1}{n} + \frac{\operatorname{pot} \mathfrak{f}_2}{m+n}. \quad . \; . \; . \; . \; . \quad (279)$$

In the case of incompressibility k, and therefore m, is infinite, so that $\mathfrak{G}_2$ is zero, and the displacement is $\operatorname{pot} \mathfrak{f}_1/n$, whatever $\mathfrak{f}_2$ may be. For $\mathfrak{f}_2$ is balanced by difference of pressure, which is set up instantly. The corresponding speed is infinite, but there is no displacement.

If, again, $m = 0$, and there is but one speed, the displacement is the potential (divided by n) of the impressed force, whatever be its type.

On the other hand, if $n + m = 0$, we see by (274) that there is no steady state possible due to divergent force, as $\mathfrak{f}_2$ is then employed simply in accelerating momentum on the spot. The corresponding speed is zero. The circuital disturbances are propagated as before. This is the case of Sir W. Thomson's contractile ether, in which the wave of normal disturbance is abolished by making the speed zero.

§ 143. We may also find expressions for the stored energy from the equation of motion. The work done and stored by the impressed force $\mathfrak{f}$ is $\frac{1}{2}\mathfrak{f}\mathfrak{G}$, though, if $\mathfrak{f}$ be put on suddenly, an equal amount is dissipated, since, $\mathfrak{G}$ being the final displacement, $\mathfrak{f}\mathfrak{G}$ is the work then done by $\mathfrak{f}$, per unit volume. Now

$$\Sigma \tfrac{1}{2}\mathfrak{f}\mathfrak{G} = \Sigma \tfrac{1}{2}\mathfrak{f}_1\mathfrak{G}_1 + \Sigma \tfrac{1}{2}\mathfrak{f}_2\mathfrak{G}_2,$$

by (264). Calling the first part U_1, and the second part U_2, we have, by (273), (274),

$$\mathrm{U}_1 = -\Sigma \tfrac{1}{2}n\mathfrak{G}_1\nabla^2\mathfrak{G}_1 = \Sigma \tfrac{1}{2}n(\operatorname{curl} \mathfrak{G})^2 \quad . \; . \; . \; . \quad (280)$$

$$\mathrm{U}_2 = -\Sigma \tfrac{1}{2}(m+n)\mathfrak{G}_2\nabla^2\mathfrak{G}_2 = \Sigma \tfrac{1}{2}(m+n)(\operatorname{div} \mathfrak{G})^2. \quad (281)$$

The transformations here used are (259) for U_1 and (249) for U_2. We see that the energy stored is expressed in terms of the squares of the rotation and of the expansion. In the contractile ether U_2 is zero, and the stored energy is U_1. We do not correctly localise the energy by the above formulæ, but only express the total amounts. For correct localisation

Digitized by Google

we need to know the stress and the distortion. Now the distortion is a function of the variation of displacement, so is known in terms of $\mathbf{G}$. Can we, however, find the stress itself from the equation of motion? If not, we can come very close to it. Thus, in a state of equilibrium, $\mathbf{F}+\mathbf{f}=0$, if $\mathbf{F}$ is the force arising from the stress. So, by (275), (276),

$$\mathbf{F}_1 = n\nabla^2\mathbf{G}_1, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (282)$$

$$\mathbf{F}_2 = (n+m)\nabla^2\mathbf{G}_2, \quad . \quad . \quad . \quad . \quad . \quad (283)$$

and

$$\mathbf{F} = n\nabla^2\mathbf{G} + m\nabla^2\mathbf{G}_2. \quad . \quad . \quad . \quad . \quad (284)$$

Now let $\mathbf{P}_N$ be the stress on the plane whose normal is $\mathbf{N}$. We have, by consideration of the equilibrium of a unit cube,

$$\mathbf{FN} = \operatorname{div}\mathbf{P}_N, \quad . \quad . \quad . \quad . \quad . \quad . \quad (285)$$

to express the relation between an irrotational stress and the force arising from it. Therefore, applying this to (284),

$$\operatorname{div}\mathbf{P}_N = n\nabla^2\mathbf{GN} + m\nabla^2\mathbf{G}_2\mathbf{N}. \quad . \quad . \quad . \quad (286)$$

Here the divergence of $\mathbf{P}_N$ is given; find $\mathbf{P}_N$ itself. The immediate answer is, by (201), or (214),

$$\mathbf{P}_N = -\nabla\operatorname{pot}\operatorname{div}\mathbf{P}_N,$$

or

$$\mathbf{P}_N = n\nabla\mathbf{GN} + m\nabla\mathbf{G}_2\mathbf{N}, \quad . \quad . \quad . \quad (287)$$

provided $\mathbf{P}_N$ is divergent. That is, we have constructed a stress-vector giving the proper force required. But, without interfering with this essential property, we might add on to the right side of (287) any circuital vector. That we must do so now, we may see by remembering that the stress must be irrotational, or produce no torque, and then by finding that (287) does give a torque. To show this, consider the first part only of the stress (287), say with $m=0$. Then

$$\mathbf{NP}_M - \mathbf{MP}_N = n(\mathbf{N}\nabla.\mathbf{MG} - \mathbf{M}\nabla.\mathbf{NG}).$$

Here take $\mathbf{M}=\mathbf{j}$ and $\mathbf{N}=\mathbf{k}$; then

$$\mathbf{kP}_j - \mathbf{jP}_k = n(\nabla_3 G_2 - \nabla_2 G_3) = -n\operatorname{i}\operatorname{curl}\mathbf{G},$$

by (149). This gives the $\mathbf{i}$ component of the torque, which is therefore $-n\operatorname{curl}\mathbf{G}$. But $\mathbf{G}_2$ has no curl, therefore the second part of (287) produces no torque. We require, therefore, to add to $\mathbf{P}_N$ in (287) a stress giving no force, but a torque $n\operatorname{curl}\mathbf{G}$. Such a stress is

$$\mathbf{X}_N = n\operatorname{curl}\mathrm{V}\mathbf{GN} \quad . \quad . \quad . \quad . \quad . \quad (288)$$

as may be tested in the above manner.

This brings us from (287) to

$$\mathbf{P}_N = n(\nabla\mathbf{GN} + \operatorname{curl}\mathrm{V}\mathbf{GN}) + m\nabla\mathbf{G}_2\mathbf{N}, \quad . \quad . \quad (289)$$

which is a stress-vector giving the correct force and no torque. But on comparison with the real stress deduced from the elastic properties of a solid, which is

$$\mathbf{P}_N = n(\nabla.\mathbf{GN} + \mathbf{N}\nabla.\mathbf{G}) + \mathbf{N}(m-n)\operatorname{div}\mathbf{G} \quad . \quad . \quad (290)$$

we see that they do not agree. Yet they can only differ by a stress which produces neither force nor torque. And we know already, by (288), that if $\mathbf{G}=\mathbf{G}_2$, the modified stress will give no force or torque. In fact, on comparing (289), (290), we find that their difference is of this nature, (290) being equivalent to

$$\mathbf{P}_N = n(\nabla\mathbf{GN} + \operatorname{curl}\mathrm{V}\mathbf{GN}) + m(\nabla\mathbf{G}_2\mathbf{N} - \operatorname{curl}\mathrm{V}\mathbf{G}_2\mathbf{N}), \quad (291)$$

where the first and third terms on the right are sufficient to give the correct force, but with a torque, which is, however, cancelled by the second term; whilst the fourth term is apparently (so far as force and torque are concerned) like a fifth wheel to the coach, off the ground. If we inquire under what circumstances the real stress can assume this singular form, we shall find that $m+n=0$ and $\operatorname{curl}\mathbf{G}=0$ will do it. With these conditions, only the circuital part of $\mathbf{P}_N$ is now left, and (291) reduces to

$$\mathbf{P}_N = 2n\operatorname{curl}\mathrm{V}\mathbf{G}_2\mathbf{N}. \quad . \quad . \quad . \quad . \quad (292)$$

It is the case of irrotational displacement in the contractile ether, previously referred to, and is entirely remote from the real elastic solid. The noteworthy thing is that we cannot apparently conclude what the stress is, even when the force and torque to correspond are everywhere given, owing to the forceless and torqueless stress coming into the formulæ. The form (292) is convenient for showing at sight that there is no force. It may, by (181), remembering the constancy of $\mathbf{N}$, be expanded to

$$\mathbf{P}_N = 2n(\mathbf{N}\nabla.\mathbf{G}_2 - \mathbf{N}\operatorname{div}\mathbf{G}_2), \quad . \quad . \quad . \quad (293)$$

where put $\mathbf{N}=\mathbf{i}, \mathbf{j}, \mathbf{k}$ in turns to get the three stresses on the planes having these normals. One-third of the sum of the normal tractions on these planes is $-(4n/3)\operatorname{div}\mathbf{G}_2$, or, which is the same, $+k\operatorname{div}\mathbf{G}$. It is the negative of the pressure. But in the real stress (291) itself, the fourth part, from its having the negative sign prefixed, correctly associates pressure and compression. But this forceless and torqueless stress does not contribute anything to the total energy. The amount of stored energy is

$$\begin{aligned}\Sigma\tfrac{1}{2}\mathbf{fG} &= -\Sigma\tfrac{1}{2}\mathbf{FG} = -\tfrac{1}{2}\Sigma(\mathbf{F}_1\mathbf{G}_1 + \mathbf{F}_2\mathbf{G}_2 + \mathbf{F}_3\mathbf{G}_3)\\ &= -\tfrac{1}{2}\Sigma(\mathbf{G}_1\operatorname{div}\mathbf{P}_1 + \mathbf{G}_2\operatorname{div}\mathbf{P}_2 + \mathbf{G}_3\operatorname{div}\mathbf{P}_3)\\ &= \tfrac{1}{2}\Sigma(\mathbf{P}_1\nabla\mathbf{G}_1 + \mathbf{P}_2\nabla\mathbf{G}_2 + \mathbf{P}_3\nabla\mathbf{G}_3), \quad . \quad . \quad . \quad . \quad (294)\end{aligned}$$

where the first line needs no remark, the second is got by (285), and the third by the common transformation (249), $\mathbf{P}_1$, etc., being the stresses on the $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$ planes. The final form in (294) shows the correct distribution of the energy in terms of the stress and the distortion. Now, if in the stress $\mathbf{P}_N$ be included any terms giving rise to no force, the above transformation shows that they contribute nothing on the whole to the energy of distortion. This is the case with the fourth term in (293), and would also be the case with the second term, only that we have no right to ignore it, on account of the torque thereby brought in. If the solid be not unbounded, it is sufficient for its boundary to be at rest for the same principles to apply.

§144. The simple solution (279) may, of course, receive many other forms. If it be desired to find the displacement due to an explicitly given impressed forcive, it is a matter of some importance to select a method of obtaining it which shall not be unnecessarily difficult in execution; for different processes leading to the same result may vary greatly in readiness of application. Now, if the impressed forcive be either circuital or divergent, we do not need to modify. But if of a mixed type, then it may be desirable. Put $\mathbf{f}_1 = \mathbf{f} - \mathbf{f}_2$, then an alternative form is

$$\mathbf{G} = \operatorname{pot}\left(\frac{\mathbf{f}}{n} - \frac{m\mathbf{f}_2}{n(m+n)}\right); \quad . \quad . \quad . \quad (295)$$

and now, when $\mathbf{f}$ is given, it is only the part $\operatorname{pot}\mathbf{f}_2$ that needs development. We have

$$\mathbf{f}_2 = \Sigma\mathbf{r}_1\operatorname{div}\mathbf{f}/4\pi r^2 = \Sigma\nabla p\,.\operatorname{div}\mathbf{f}, \quad . \quad (296)$$

as before explained. Now, if we notice that

$$\nabla^2 r = 2/r, \quad . \quad . \quad . \quad . \quad . \quad (297)$$

which may be proved by differentiating, we can further conclude that

$$\operatorname{pot}(\mathbf{r}_1/4\pi r^2) = \mathbf{r}_1/8\pi, \quad . \quad . \quad (298)$$

a very curious result. The potential of a radial vector following the inverse-square law of intensity is a radial vector with a constant tensor in all space. Using this result, we have

$$\operatorname{pot}\mathbf{f}_2 = \Sigma\mathbf{r}_1\operatorname{div}\mathbf{f}/8\pi, \quad . \quad . \quad . \quad (299)$$

so that (295) becomes

$$\mathbf{G} = \frac{1}{n}\operatorname{pot}\mathbf{f} - \frac{m}{n(m+n)}\Sigma\frac{\mathbf{r}_1\operatorname{div}\mathbf{f}}{8\pi}, \quad . \quad (300)$$

wherein $\mathbf{f}$ alone appears on the right side.

Another form is got by using

$$\mathbf{f}_2 = \nabla\Sigma\mathbf{f}\nabla p, \qquad \therefore \operatorname{pot}\mathbf{f}_2 = \nabla\operatorname{pot}\Sigma\mathbf{f}\nabla p. \quad (301)$$

But a better one is

$$\operatorname{pot}\mathbf{f}_2 = -\Sigma f\nabla\frac{dr}{ds}8\pi, \quad . \quad . \quad . \quad . \quad (302)$$

where s is length measured along $\mathbf{f}$, and f is the tensor of the latter. This makes

$$\mathbf{G} = \frac{1}{n}\operatorname{pot}\mathbf{f} + \frac{m/8\pi}{n(m+n)}\Sigma f\nabla\frac{dr}{ds}, \quad . \quad . \quad (303)$$

which is generally suitable for practical calculation.

Digitized by Google

A considerably more complex form is given in Thomson and Tait. It may be obtained from (303) by means of the identity

$$\nabla \frac{dr}{ds} = \frac{2}{3r}\mathbf{s}_1 - \frac{r^2}{3}\nabla \frac{d}{ds}\frac{1}{r}, \quad \ldots \quad (304)$$

where $\mathbf{s}_1$ is unit $\mathbf{s}$, and therefore parallel to $\mathbf{f}$, making

$$\mathbf{G} = \text{pot } \mathbf{f}\left(\frac{1}{n} - \frac{m}{3n(m+n)}\right) + \frac{m}{24\pi n(m+n)} \Sigma f r^2 \nabla \frac{d}{ds}\frac{1}{r}, \quad (305)$$

the same as Thomson and Tait's formulæ when expanded in cartesians. But this is a gratuitous complication, as (301) is simpler in expression and in application. Of course (300) is simpler still in expression, and the practical choice may lie between it and (303), or (295).

Notice that an impressed forcive of the divergent type with a single point-source produces not merely uniform radial displacement, as per (298), but an infinite discontinuity, in fact, a disruption, at the source itself. It is a very extreme case, of course.

(To be continued.)

NOTES ON NOMENCLATURE.

By way of preparation for the International Electrical Congress which it is proposed to hold at Chicago in September, 1893, M. Hospitalier delivers himself in a recent number of *L'Industrie Electrique* of a few observations on his favourite theme of logical electrical nomenclature. M. Hospitalier, as it has been remarked, is "the soul of method" in this matter; and we cannot, therefore, do better than give our readers the benefit of his opinions in full:—

My first observation relates to the too marked national individualism exhibited by the representatives of the different nations brought together with a view of coming to international decisions, and the repugnance which they show to enforce these decisions in every-day work when they do not happen to give entire satisfaction to national *amour propre*.

Up to 1881 the practical unit of resistance was the B.A. ohm, represented by the resistance of a column of mercury 104·8cm. long and 1 sq. mm. cross-section at the temperature of melting ice. As a result of the Congress of 1881, the International Conference appointed to consider the length of the column of mercury representing the ohm, defined as equal to 10^9 C.-G.-S. units, more accurately decided that the length should be 106cm., and gave it the name of *legal ohm*. But the legal ohm has never been accepted in England, and for some years the English have adopted, under the title of *true ohm*, the resistance of a column of mercury of 106·3cm.

Let me remark that the term *true ohm* is a deplorable one, and absolutely incorrect, since the true ohm is by definition equal to 10^9 C.-G.-S. units, and has for us only an asymptotic value. We shall approximate the true value more and more by determinations more and more accurate, but we shall never actually reach it. The first mission of the Chicago Congress will, therefore, be to evolve some degree of order out of this chaos of B.A., *legal*, *true*, and other ohms.

The 1889 Congress gave the name of *quadrant* to the unit of self-induction, and defined it as follows:—One *quadrant* = 10^9 C.-G.-S. units of self-induction. This name formed an exception to the rule adopted in 1881 with regard to the nomenclature of units. It was everywhere badly received, and it is nearly certain that the Chicago Congress will sanction the name of *henry* in place of the term *quadrant*, which designates more particularly a length equal to 10^9cm.

The 1889 Congress adopted the terms *watt* and *joule* respectively for the volt-ampere and the volt-coulomb; but it is only since the Frankfort Congress of 1891 that the Germans have partially given up the volt-ampere and volt-coulomb.

My second remark relates to the useless creation of new names. I consider that the *rôle* of a Congress is to fix for all time the name of a new physical quantity or of a new unit each time that it is necessary to do so, but not to indefinitely multiply these names to the annoyance of those who have to use them. The Board of Trade has afforded us a case in point. When the question arose of selling electrical energy supplied from central stations, and of devising an appropriate unit, the Board of Trade decided to take as its unit the energy corresponding to a current of 1 ampere at a difference of potential of 1,000 volts, lasting one hour,* and it unfortunately baptised it in the senseless name of *unit*—a name short indeed, but one which in practice has become, in order to avoid confusing it with other units of energy, the *Board of Trade unit*. Recently, this name appearing cumbersome, it was proposed to call this unit the *kelvin*, a proposition which was immediately withdrawn at the request of the godfather, Lord Kelvin (Sir William Thomson), who suggested the term *supply unit*. I may, perhaps, be allowed to remark that all these names are utterly useless. Since the units watt and hour have an official and legal character, and since the prefix *kilo* has been adopted by all nations as indicating multiplication by 1,000, it is both simple and logical to call the energy corresponding to 1,000 watts during an hour the *kilowatt-hour*. If people prefer to adopt in practice a unit ten times smaller, as is generally done in France, this unit of energy will be called the *hectowatt-hour*; and all the world will understand what is meant without any further explanation, and without burdening the memory.

As a general rule, physical quantities and their units should be formed by successive definitions, and should not bear special names unless the compound word is too long or too difficult to pronounce, which is not the case in regard to the kilowatt-hour.

[* The following is the actual definition:—The expression "unit" shall mean the energy contained in a current of 1,000 amperes flowing under an electromotive force of 1 volt during one hour.—ED. *E.*]

BOOKS, &c., RECEIVED.

"Dynamo-Electric Machinery. A Manual for Students of Electrotechnics." By Silvanus P. Thompson, D.Sc., B.A., F.R.S. Fourth Edition. Enlarged and revised. (London: E. and F. N. Spon.)

STEEL-PLATE PORTRAITS

Of W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Baron Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz and Prof. W. E. Ayrton (President of the Institution of Electrical Engineers), have been issued as Supplements to "THE ELECTRICIAN."

A few Copies of these admirably-executed Steel Engravings can be supplicp price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, 4s. 6d, carriage paid (U.K.)

MISPLACED INVENTIONS.

The development of the electrical industry in opening fresh fields for the play of invention has been accompanied by a waste of ingenuity such as the history of arts and manufactures has probably never before witnessed, so easy is it to scheme ways of doing this or that by electricity. The devising and experimenting are fascinating to some minds; and too often the practical value of the idea is lost sight of, and the satisfactory working of a model is confounded with a commercial success. While the numberless arc-lamp movements which have been invented during the past twelve or fourteen years are a remarkable example of such squandered ingenuity, the waste of time is not so serious as in other matters, for the large majority of the inventors have been ignorant of the conditions of the problem; they merely fumbled with magnets and bungled with escapements, and were good for little else. The result of their labours is a hundred or two of nearly hopeless failures, a score of passable lamps and three or four excellent ones. The attempts were excusable, for a good arc lamp was wanted.

Another favourite problem is the station indicator for trains. There are three propositions concerning the station indicator: firstly, there are few, if any, in daily use; secondly, some passengers would appreciate them; and thirdly, "it can be done by electricity." That is quite sufficient for the unhappy inventor; and he sets to work with bands on rollers,

Digitized by Google

fingers on dials, or even pointers on maps, and makes a model that will work. But the railway companies fail to see in what way the adoption of the system will add a shilling to their revenue, even if the apparatus were presented to them and fitted free of cost; while it would be liable to get out of order and deceive their passengers. If the station indicator could be combined with "a penny-in-the-slot" there might be some inducement for the railway companies to take it up; but "a twopence-in-the-slot" speaking-tube, communicating with the guard, would be better, one of the pennies, of course, going to the guard; but there would be no excitement in inventing that, neither ingenious mechanisms nor electricity would be wanted. Sending pictures and writing by telegraph has attracted a few dozen inventors; it can be done whenever there is a demand. Telegraphic or telephonic communication between railway passenger, guard, engine-driver and signalmen, has been devised over and over again; and because it has never been seriously put in practice there are always inventors who think that it has never been proposed. Probably, not one in twenty of these patentees have ever travelled on an engine, or have any idea even of the kind of electric bell which would be suitable for fixing in such a situation. We have ourselves intercepted a semaphore message of a strictly domestic character relating to a frying-pan, sent by a coastguard while on duty; but the work of a coastguard differs considerably from that of an engine driver. It would, no doubt, be a great scientific triumph, which would be duly paragraphed into fame by the daily papers, if the driver of an express could ask to be "put through" to the general manager and tell him that as he had learned from the signalmen that the line was clear ahead for about 70 miles, he would like to take the opportunity of expressing his views on the eight-hours question. We should be sorry, however, to travel behind that driver if the signalling were dependent on sliding contacts and insulated mid-rails.

Many of the inventors to which we have alluded are either amateurs or have gone to work in an amateur fashion. Such men have a literature of their own, and societies of their own; some few have an incurable mania for invention, associated too often with a carelessness of expression which is liable to be confounded with deliberate falsehood. There are, however, plenty of examples of misapplied work among professional men, and in these the error is often in the application rather than the thing itself. A man makes motors, and he wants to find a new market for them; he fits one up in combination with a winch or capstan of a ship, without perhaps the smallest knowledge of the way in which winches are handled when at work, or the usages to which they are subjected at other times. Another man, in happy ignorance of the practical details of railway working, sets himself down to design, say, an electric locomotive which shall "whip creation," with the result that it beats the record, though scarcely in the manner expected by the sanguine inventor. But instances of misplaced ingenuity are as the sands of the sea-shore.

Invention is an art, in so far that it is an exercise of originality, and that it is sometimes of the nature of an inspiration; for this reason, together, perhaps, with the fact that it is occasionally rewarded by substantial profits, an unwarrantable importance has been attached to it. But invention unaccompanied by research and discovery does not call for any high order of intellect, and often has a mischievous effect on temperament and character. The statistics of invention as a business are impossible to arrive at, but it is not improbable that if dissociated from the commercial genius which is generally contributed, not without due reward, by someone else, more money is lost than is made by miscellaneous inventing. On the whole, therefore, the best advice to give to those about to invent is "Don't." We are afraid, however, that there is as little likelihood of this cautious counsel being taken to heart by inventors as there is of its being listened to by those to whom it was originally addressed. Three golden rules may, perhaps, be laid down: first, make sure your panacea is wanted, and that the game is worth the candle; then make sure that no one else has thought of it before; lastly, make yourself thoroughly acquainted with the practical working conditions of the problem to be solved. Then, and not before, it will be time enough to sit down and circumvent prior patents and the difficulties of the case.

REVIEWS.

A Treatise on Electricity and Magnetism. By JAMES CLERK MAXWELL. Third edition, 1892. (Oxford: Clarendon Press.)

This work consists of a carefully revised reprint of the second edition, published ten years ago under the direction of Mr. W. D. Niven. The pressure of other duties has rendered it impossible for Mr. Niven to see the present edition through the press, and Prof. J. J. Thomson has accordingly undertaken the task. It was the original intention of the editor to supply in the form of foot-notes some account of the great advances made in the science of electricity since the publication of the first edition of this work 20 years ago. The unparalleled extent of the changes during this period, due in no small degree to the views introduced by Maxwell's great work, are, however, such that Prof. Thomson's idea could only have been carried out by considerably increasing the bulk of the book. Rather than do this it has been thought preferable to issue a "supplementary volume," the publication of which is promised shortly. Probably far more will be expected of this new work than any single volume can supply; but, in the meanwhile, the foot-notes and additions made in the present reprint are neither few nor unimportant. One of the appendices contains a description of Maxwell's method of determining the self-induction of a coil, reprinted from his classical Paper on the Dynamical Theory of the Electro-Magnetic Field. This method, although invented and described in the *Phil. Trans.* for 1865, or nearly thirty years ago, is now for the first time published in an easily accessible form. Another valuable extract from the same Paper appears on page 245, as a note to Chapter VIII., dealing with the investigation of the magnetic field. Mr. Heaviside's assumption that all electric currents flow in closed circuits, which leads to certain great simplifications in the equations representing the magnetic state of the field, is also discussed in a lengthy mathematical note. An appendix, several pages in length, is inserted at the end of Chapter IX., and other appendices occur.

An important mathematical addition on pp. 323-5 deals with the subject of the distribution of the current in conductors subjected to the action of rapidly-changing electromotive forces; but it is hardly fair that the name of Prof. Hughes should be omitted in reference to this matter. Maxwell clearly pointed out in mathematical language the influence of self-induction in causing alternate currents to crowd towards the outer parts of conducting wires. But no one paid any attention to this matter, or had any numerical idea of the extent to which this effect took place, till Prof. Hughes, with marvellous experimental skill, detected the effect, and brought it into public notice in his Presidential Address to the Society of Telegraph Engineers in 1886. The interpretation of the measurements made, owing to the novelty and difficulty of the subject, was somewhat confused at the time, as was indeed evidenced by the lengthy discussion which took place after Prof. Hughes's Paper. One result was, however, to induce Lord Rayleigh to take up the subject mathematically; and he found, what no one seemed to have previously suspected, that this since-called "skin effect" could, under certain circumstances, become of marked importance. If, however, Prof. Hughes had not made his experiments, it is probable that mathematicians, when recalling this effect, would consider it

Digitized by Google

altogether negligible, and that all others would be ignorant of its existence.

Prof. Thomson makes several brief references to recent experimental work which has tended to confirm the views of Maxwell, or which illustrates or modifies the statements made in the work. Thus we notice, among others, an allusion to Helmholtz's restriction to Thomson's law for deducing the electromotive force of a cell from the heat-equivalents of the chemical combinations occurring within the cell. The Hall effect is referred to in connection with those passages of Maxwell's work whereon it bears, and Ewing's researches are alluded to in the chapter on Magnetism. In the chapter on the Electro-Magnetic Theory of Light several references naturally occur to recent work, but these are not so numerous as might have been expected. On page 436 a long list of determinations of "v" is inserted. On page 438 reference is made to measurements with electrical oscillations, tending to verify the law connecting the refractive index of a substance with its specific inductive capacity; and on page 441 a lengthy and valuable note is added explaining the nature of the forces exerted by light when incident on a reflecting surface.

Prof. Thomson has not always been able to verify the results which Maxwell gives without proof, and occasionally remarks of a critical nature have been added about the reasoning used in the text. Perhaps the most important of these criticisms is that on page 192, dealing with the deductions of the equations of induction from the principle of the conservation of energy.

While a reissue of Maxwell's great treatise, to be followed soon by a supplementary volume, is very satisfactory in itself, what is, perhaps, more generally required is a brief, clear statement of what Maxwell's theory really consists. The greater part of Maxwell's work deals with matter which is not essential to his theory of light, to which, after all, the chief value of the treatise is due. Poincaré's French Treatise on *Electricité et Optique*, and Hertz's German reprint of his remarkable researches on electrical oscillations, are the most recent outcome of the electro-magnetic theory. It seems very strange that there does not exist in English any connected account, free from the presence of extraneous matter, of what this theory actually is.

Die Akkumulatoren für Elektricität. By EDMUND HOPPE. One vol. Second edition. (Berlin: Julius Springer. 1892.)

This is the most complete work on the subject we have yet seen. Starting with the discoveries of Humboldt and Dr. Ash in 1797, a summary of the principal work done on the subject of electrolysis, and the theories which have been founded on it are given, and the work is brought very well up to date. Then follows a chapter on the secondary reactions produced by the current and "polarisation." References are very freely given all through, and the credit due to the different workers is fairly apportioned on the whole, though English readers will probably be inclined to claim a little more for their own countrymen. The second part of the book deals with the construction of commercial reversible batteries, starting with Planté's, and describing the leading derivatives from this and the Faure cell, and the various other types which have been suggested from time to time. A list of the principal patents is given, with dates of expiry and names of present holders as far as possible, which should be of great value to manufacturers. Following this is a section devoted to the researches which have been made on the chemistry and efficiency of the batteries. This portion of the work is particularly valuable, as the introductory chapters have made clear the grounds on which the various theories put forward are based, so that it is possible to follow the arguments advanced in support or contradiction of them. The next section deals with the tests which have been made on cells by particular makers from time to time, and the work concludes with a section devoted to the varions applications of reversible batteries to electric lighting, traction, telegraphy, &c., and the best disposition of them for each purpose. The book is well and clearly illustrated, numerous tables are given, and altogether a vast amount of information has been got into a small compass.

Secondary Batteries. By J. T. NIBLETT.

We have received from the author a copy of this book, which is, as stated on the title-page, "A Description of the Modern Apparatus for the Storage of Electrical Energy," and is mainly a reprint.

All the leading cells of the lead, lead-zinc, alkaline, and other types are described, and many which have heretofore remained buried in the obscurity of the Patent Office; but as the descriptions are not full enough, in most cases, to enable a would be patentee to discover whether his idea has been anticipated or not, it strikes one that the value of the book would be much enhanced to the practical man if the date and number of the patent referred to, as well as the name of the inventor, were given in a future edition. Concerning the chemistry of the cell very little is said, but the value in reducing sulphating of the addition of soda to the electrolyte, as suggested by Mr. Barber Starkey, is pointed out. In the appendix will be found some information regarding the chemical properties of the materials used in the construction of secondary batteries.

A Manual of Physics, being an Introduction to the Study of Physical Science, designed for the use of University Students. By W. PEDDIE, D.Sc., F.R.S.E. (London: Baillière, Tindall and Cox).

This text-book, of which we give the full title and description appearing on the title page, is intended to review the principles of the subject in one small volume, and yet it cannot be said to be in any sense an elementary work, but is addressed to readers who already enjoy a very fair knowledge of not only pure, but of applied, mathematics and quaternions. The book would be very useful to students who have deferred their study of physics until they have made considerable advance in mathematics; but the majority begin with an elementary course, for which this work is not suited, and in the more advanced classes, separate books upon the various subjects are indispensable. The chapters on electricity and magnetism are very incomplete, and contain no reference whatever to recent knowledge; and while we cannot expect to find any account of practical applications, the elementary scientific principles which underlie the telephone and the dynamo might at least be referred to.

General students will find one or two sections of considerable interest, *e.g.*, a chapter on the theory of contours and triangular co-ordinates, and some notes on fluid motion and dilatancy.

Electric Lighting for Marine Engineers. By SIDNEY F. WALKER. (London: Tower Publishing Company. 1892.)

Although the aims of this book, as set forth in the preface, are modest, since young electrical engineers are addressed, the author discusses the whole subject of electric lighting, together with an elementary introduction. He advises the use of belt driving from engines running at 200 to 250, and recommends a regulating apparatus, since "it is a very difficult thing indeed to compound machines exactly." The few observations on alternate current work are rather misleading. The old wooden lampholders with looped wire springs are described with hardly a word of warning; and this in a book on ship work! Twenty illustrations of lampholders and forty-one of switches, many of them having been invented by the author, are no indication of completeness or even value. The chapter on measuring instruments does not contain a word about the spring control which is essential for ship work. The Cardew voltmeter is dismissed in seven lines as "quite unsuitable for 'board ship' work." As a matter of fact, though not perhaps the best for this purpose, it is the only one of those described which would be any use at all on board ship. The book as a whole is sadly old-fashioned and full of errors.

Blowpipe Analysis. By J. LANDAUER. Translated by J. TAYLOR. (London: Macmillan and Co.)

This little book is very clearly written. The arrangement of the contents leaves little to be desired, and the illustrations are good. Students already in possession of one of the modern large works on qualitative analysis will not find much with which they are unfamiliar, but to others the work should prove of value, more especially as examples for practice are included. The tables at the end, giving a condensed view of the blowpipe reactions, will be of use to all.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 93.*)

11. Picking-up Gear.—Having glanced at the tanks, and formed some idea of their capacity for different types of cable, we should now, as the ship is supposed to be nearly up to the fault, spend the rest of our time on deck. Here the cable is still coming inboard, and our attention may well be given for a few moments to the action of the steam picking-up gear. This is fixed forward of the bridge, and in some ships is placed upon, and in others immediately below the upper deck. Space is always a consideration on board, and the gear is usually of very compact design, so as to take up as little room as possible. On this account it will be found to require some close observation to understand and appreciate the uses of every part of the gear.

The large winding drum and the various shafts, cog-wheels, and pinions are all seen revolving in their respective positions, and there are various levers and hand-wheels used either in controlling the brakes, varying the speed of the drum, starting or reversing the engines, or throwing in and out of gear. For the purpose of examining the principal parts composing such gear,

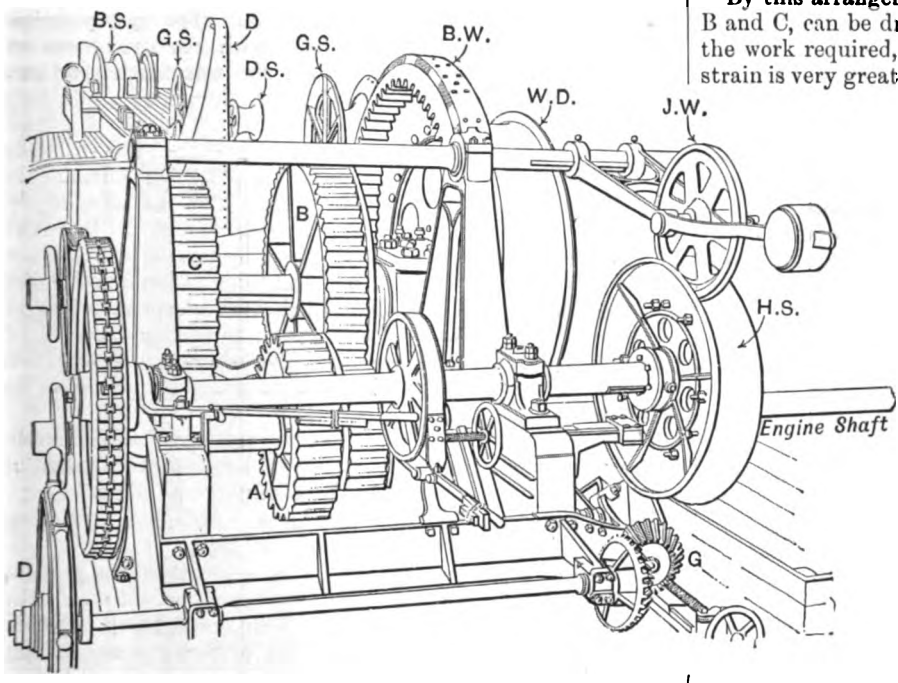

FIG. 34.—Picking-up gear on cable ship "Dacia."

an illustration is given in Fig. 34 of the picking-up gear used on board the cable ship "Dacia," belonging to the India Rubber, Gutta Percha, and Telegraph Works Company.

This perspective view takes in all the machinery as far as the bows, and the path of the cable from the bows to the tank can be well traced. The cable comes in over the bow sheave B S, then passes over the guide sheave G S, under dynamometer sheave D S, over a second guide sheave, then takes three or four turns round the winding drum W D, and thence passes over the sheave H S to the tank. The gear receives motion rom a small steam engine, which drives the engine shaft indicated in the figure through a speed-reducing gear.

The drum is only required to run very slowly, at most about twelve revolutions per minute, a considerable amount of purchase being obtained by the intermediate train of speed-reducing gear between the drum and the engine. The latter is generally designed to run at 100 to 150 revolutions per minute, and the speed is in some cases reduced by one or two intermediate shafts, with pinions driving spur wheels, and in others by a large wheel on the first motion shaft, and a pinion on the engine shaft driving it. The gear is designed to stand at least ten times the strain it will ever be subjected to, and the strength of the teeth is calculated accordingly. The wheels are generally of good malleable cast iron, but in some of the more modern sets they are made of cast steel, by which four times the strength and one-twelfth the weight of similar wheels of cast iron are obtained. Gear designed with cast steel wheels is, therefore, much lighter, and takes up less room for the same power.

For convenience in dealing with work involving different strains a single and double purchase is always fitted on the gear. The single purchase, of course, runs the drum at the quicker speed, and is used in the lighter strains; while the double purchase is used in the heaviest work and drives the drum at half the speed. In the gear illustrated this is effected by the spur wheels at A, B and C. The pair of wheels at A on the first motion shaft are of different diameters, and are either bolted together or cast in one. They can be shifted together along the shaft, so that the large wheel engages with C, or the small wheel with B, the latter position, as they are shown set in the illustration, being that of double purchase. The shifting of the pair is done by turning a hand-wheel and screw, or lever, causing a fork which engages in a collar fixed to the pair of wheels to travel along the shaft and carry the wheels with it. The wheels skid over a long key or feather on the shaft.

By this arrangement the drum shaft, on which are the wheels B and C, can be driven at two convenient speeds, according to the work required, while the engine speed is the same. If the strain is very great, as in heaving up cable from 2,000 fathoms, the slow gear is put on, a greater purchase is thereby attained, and a greater load can be lifted by the engine, because it now lifts it slower. The same thing would not, of course, be attained by slowing down the engine, since that would mean a decrease of power consequent upon either an earlier cut off in the cylinder, or a decrease in the volume and pressure of steam admitted. This change from single to double purchase is, of course, only made when the engine and gear are at rest. It can generally be judged before starting which gear is best suited to the work in hand, but if while the gear is working it is thought better to run on the other purchase, it is a simple matter to put on the brake and slow down the engine at the same time, and when stopped shift over and start up again. Sometimes, as in slacking or paying out, it is necessary to let the gear run free of the engine altogether and use the brake, in which case the pair of wheels can be put to the intermediate position between B and C when they are not in gear with either.

The brake wheel is on the same shaft as the drum, and is about 7ft. in diameter. Outside it (as shown at B W) is the brake strap, consisting of a band or hoop of flat iron with wood blocks screwed on at intervals. The blocks bear on the face of the wheel, and the friction on the same can be regulated by tightening gear, which closes up the band. In the figure the hand-wheel for regulating the brake is shown at D, the motion to this wheel being transmitted to the brake band by two bevel pinions on the right. The lower half of the brake-wheel revolves in a tank of water.

As the cable comes in past the drum, it is necessary to keep it in a straight line and perfectly taut, or it will not run evenly over the drum. For this purpose it is led over the sheave H S before passing into the tank. Over this sheave is a smaller wheel, mounted in a bracket keyed to a shaft, as shown, and which is weighted by the counterweight fixed at the end of the bracket. This wheel, called the jockey wheel, is chamfered off on both sides of the face, so as to fit easily in the groove of the sheave when the cable is passing over it, and its duty is to exert a pulling action on the cable in the direction in which it is moving, and so keep it from slipping back or sagging. In order to effect this properly, the sheave H S is driven a little faster than the drum, so as to draw the cable off the drum and

* All rights reserved.

Digitized by Google

keep it taut. That is, the circumferential speed is a little greater than that of the drum. For example, if the drum was 18ft. in circumference, and ran at 10 revolutions per minute, the cable would leave the drum at a speed of 180ft. per minute, and the jockey sheave would have to take charge of it, and pull it in at a little faster speed to keep it taut, say at 185ft. per minute. Hence, if the sheave had a circumference in the groove of 5ft., it would have to be geared to run at 37 revolutions per minute, or nearly four times the speed of the drum. Of course the sheave slips past the cable a little, due to the slight excess of speed, but by this means, together with the weight of the jockey wheel riding on it, the cable is kept perfectly taut. The jockey sheave is always run by gearing off the drum shaft, not the engine shaft, as thereby the ratio of speed between the drum and jockey is maintained the same, irrespective of the intermediate gear between the engine and drum. This will be noticed in the illustration, where the shaft on which the jockey or hauling sheave is mounted is driven by a pitch chain wheel on the left-hand side. The further chain-wheel, which drives the above, is keyed to a shaft driven by a pinion gearing into the teeth on the inside of the brake wheel. By this means the necessary speed of the jockey sheave is obtained, while at the same time the brake wheel, being on the drum shaft, imparts to the jockey, through the pitch chain gear, a speed bearing a constant ratio to that of the drum. After leaving the jockey sheave the cable passes down into the tank through an eye fixed to a piece of timber across the hatch (Fig. 35). This is of use in both coiling in

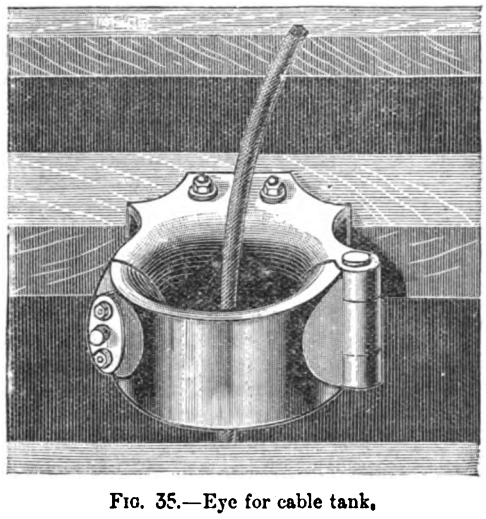

Fig. 35.—Eye for cable tank.

and paying out cable, in keeping it exactly over the middle of the tank. The eye is cast in two halves, one half being bolted to the cross timber, and the other hinged to it, so that it can be opened at any time, when it is required to slip cable out. This is necessary, for instance, during paying out, if it is required to change over and pay out from another tank.

Further, with reference to the jockey gear, it may be mentioned here that when paying out either grapnel rope or cable over the bows, it is necessary that the cable or rope should be held back, in order to feed it taut on to the drum from the tank. The jockey-pulley and sheave perform this duty also; but in this case, contrary to the conditions in picking-up, the circumferential speed of the jockey-sheave must be *less* than that of the drum, in order to hold the cable back. This is effected by throwing the jockey-sheave out of gear with the drum, and putting on a small brake. In the illustration the lever for putting the shaft out of gear with the pitch chain-wheel is shown at the left end of the shaft, and the brake wheel is seen mounted on the shaft about midway. The lever of the brake is set once for all to give the right amount of check or back pull on the cable as it advances towards the drum during paying out.

When cable is payed on to a drum, taking a few turns round it, it is necessary to fleet the turns or shift them constantly sideways, in an opposite direction to that in which the cable tends to coil itself on the drum. If this were not done the cable would wind itself across the drum until it reached one side, and then bank up and override the previous turns. To prevent this the fleeting knife is used against the drum, as shown in Fig. 36. The knife is of cast iron, having bolted to it on one side the curved part B, which bears against the cable. It is set close against the drum on the side on which the cable leads on, and as the drum revolves it keeps the turns constantly in the same position, and allows the cable to feed on continuously in the same place. This will be understood by reference to the figure, where the direction of winding of the cable is indicated by arrows. The knife is generally mounted on a sliding bed, so that by turning a screw (A) it can be withdrawn from the drum while the first few turns of cable are being put on. Again, if cable is led on to the drum on the other side, as in paying out, the knife is required on the other side, and the same can be shifted to the left along the bar D, by slacking the set screw C. Also the curved piece, B, can be unbolted and shifted from the left-hand side and bolted up again on the right-hand side, so as to bear against cable on the other side. In some ships—as, for instance, on the Eastern Telegraph Company's vessel, the "John Pender"—the more convenient arrangement of two knives is provided (Fig. 37), either of which can be moved up to the drum face and the other removed by the screws A A, according to which side the cable is first led on to the drum. The first occasion on which the fleeting-knife was used with the drum was on board the original "Monarch," when she was first rigged out

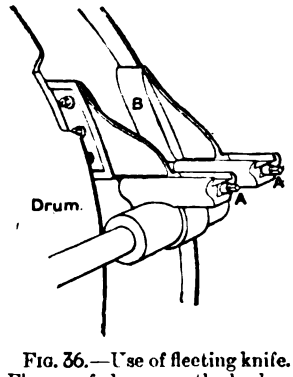

Fig. 36.—Use of fleeting knife. Flange of drum partly broken away.

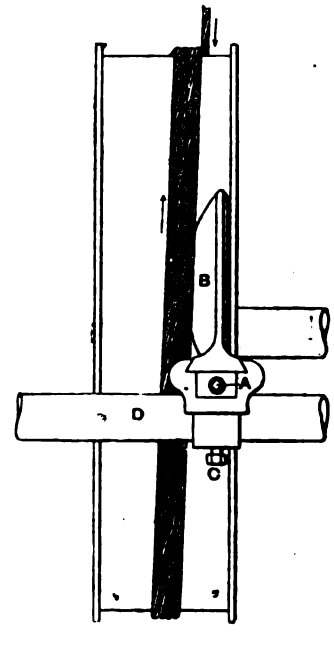

Fig. 37.—Mounting of drum knives.

to lay the Hague cables in 1853. Mr. F. C. Webb, in his interesting "Old Cable Stories Retold" (*The Electrician*, Vol. XIII., page 56), details the development in the arrangement of gear on board this 500-ton paddle steamer, which was the first cable ship fully equipped, and after whose name the present cable ship belonging to the General Post Office was christened. Mr. Webb points out that the fleeting knife, drum, and brake were made to the designs of Mr. R. S. Newall, of the firm of R. S. Newall and Co., of Sunderland, who served and sheathed the cores of the four Hague cables, and supplied the skilled labour on this the first expedition of the "Monarch." The knife had been used previously in collieries in connection with cable drums, but its first employment in submarine cable work was due to Mr. Newall. As the result of four years' work on board this vessel, Mr. Webb had gradually evolved and organised the system of picking-up and paying-out gear, cable buoys, mushroom anchors, bridles, and grapnels, the originals of those in use at the present day.

THE USE OF WATER-POWER FOR ELECTRICAL PURPOSES.

BY NORMAN F. WILSON.

In this and one or two subsequent articles we wish to give our readers some information on the subject of water-power in general, and its use in generating electricity for lighting and other purposes.

We consider this subject a most important one for electrical engineers, because cases are constantly occurring where the utilisation of water-power allows of schemes for electric lighting, &c., which would not be otherwise possible; and the rapid strides which are being made in transmitting power by electricity render serviceable many sources of water-power which are now quite useless, owing to their distance from factories or railways.

In the first of these articles we shall deal with the measuring of water, size of pipes for various quantities, horse-power to be obtained from different quantities and falls; and in the succeeding ones we shall describe two or three of the most important types of turbines. The Papers will not be severely technical; but will, we trust, be useful in enabling electrical engineers to observe for themselves when there is a likelihood of their being able to use water-power, and in serving as a guide to them in their choice of a motor.

No. I.—*Measuring Water.*

At the outset of this part of our subject we would caution our readers against guessing at the quantity of water running down a stream or millrace. It is an unwise thing for anyone to do, and often leads an engineer into difficulties. It is always best and most satisfactory to obtain some reliable measurements, even at the cost of a little time and trouble.

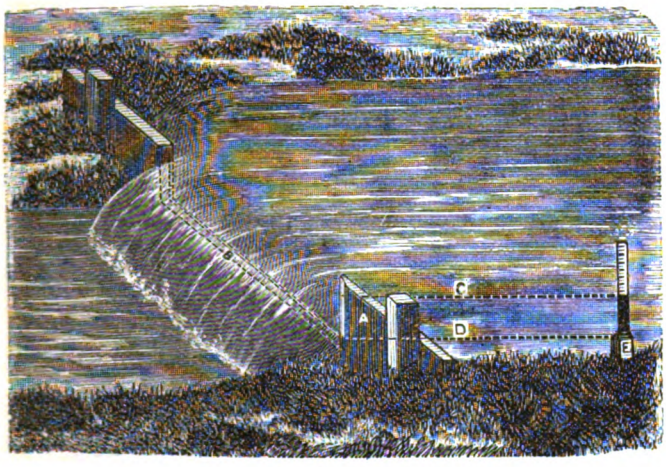

FIG. 1.

Whenever possible, with streams of moderate width we would recommend the practice of stemming the water back with a wooden dam (*see* Fig. 1), unless it is already running over a weir, or through a sluice, where it can be measured.

The planks forming the dam must have a rectangular notch B cut into them, over which the water escapes. This notch should be about two thirds the width of the stream, and the edges of the planks must be bevelled as shown, so that the water meets with no impediment. The dam must be set so that the notch is quite level, and should be high enough to impound sufficient water above it to prevent the possibility of its approaching the notch with any appreciable velocity.

A dam of this description is very easily fixed. A couple of stout pegs must first be driven into each bank, and planks laid across and stemmed with clay or sods weighted with stones. Next drive in a peg E, two or three feet higher up the stream until the top is level with the notch B. The height of water over the notch must be measured from the peg, and *not* at the notch itself, as the water begins to fall as it flows over.

By careful experiment the water (in cubic feet per minute) flowing over each foot of the notch has been found equal to $5{\cdot}15\sqrt{h^3}$, where h = height in inches; and the accompanying table has been worked out from this formula:—

Gauging Water over a Notch.

Height of water above sill.	0	¼	½	¾
0	0	·64	1·82	3·34
1	5·13	7·2	9·46	11·9
2	14·6	17·4	20·3	23·5
3	26·8	30·2	33·8	37·4
4	41·2	45·1	49·2	53·3
5	57·6	62	66·5	71
6	75·7	80·5	85·3	90·3
7	95·3	101	106	111
8	116	122	128	133

Thus, if the sill be 4ft. 6in. wide and there are 3½in. of water flowing over it, we have

$$4{\cdot}5 \times 33{\cdot}8 = 152{\cdot}1 \text{ cubic feet per minute.}$$

Another method of calculating the water in a stream or race which has a fairly regular section is as follows:—First measure a distance down the bank, say 20 yards long, and see how long a stick or bunch of grass takes to float down. This should be done two or three times, and the average speed recorded. This speed will be that at the centre on the surface, the *mean* speed of the water will only be four-fifths of this, owing to the friction of the bottom and banks. Next find the area of the cross-section of the stream. The quantity of water Q (in cubic feet per minute) is then equal to the mean velocity in feet per minute × the area in square feet. For example:—What quantity of water is flowing down a stream with a rectangular channel 7ft. 6in. wide × 1ft. 6in. deep, flowing at the rate of 2·5ft. per second on the surface?

$$\text{Area} = 7{\cdot}5 \times 1{\cdot}5 = 11{\cdot}25;$$

$$\text{Mean velocity } V = 2{\cdot}5 \times 60 \times \tfrac{4}{5};$$

$$Q \text{ in cub. ft. per min.} = 11{\cdot}25 \times 2{\cdot}5 \times 60 \times \tfrac{4}{5} = 1350.$$

When practicable, when there is any question of the water supply being deficient in dry weather, the stream should be measured over a period of some weeks, in order that the greatest, average, and least quantity flowing may be ascertained.

This will prevent any disappointment, and will enable the turbine manufacturers to put in a machine suited to the circumstances. In such cases the wooden dam is much the best, as the water can be measured two or three times a week, without any trouble, by an ordinary labourer; and a dam of this sort will remain in position for months if it be not tampered with.

After having measured the water it is very easy to find what power it will give with any fall.

It is obvious that a cubic foot of water falling a given number of feet will, neglecting friction, either raise another cubic foot an equal number of feet, or do an amount of work equal to this. A cubic foot of water weighs 62½lbs., and the power it will give for each foot of fall is therefore 62½ foot pounds. If we multiply the number of cubic feet by the fall in feet and by 62½ we get the number of foot pounds of work that a given quantity of water falling a given number of feet will do, and this result divided by 33,000 will be the theoretical horse-power; or,

When F = Fall in feet,

Q = Quantity of water in cubic feet per min.,

$$\text{H.P.} = \frac{F \times Q \times 62\tfrac{1}{2}}{33{,}000}.$$

A well constructed turbine will give 75 per cent. of this power, and a water wheel from 50 per cent. to 66 per cent.; the latter is therefore not nearly so economical as a turbine.

Allowing 75 per cent. efficiency our formula becomes:—

$$(a)\quad \text{H.P.} = \frac{F\,Q}{706},$$

Digitized by Google

or with 66 per cent. efficiency,

$$(b)\ \text{H.P.} = \frac{\text{F Q}}{802}.$$

In other words, in (*a*) 706 cubic feet per minute, and in (*b*) 802 cubic feet falling one foot will give one brake horse-power. For example:—What horse-power can be obtained from 500 cubic feet with a fall of 23 feet?

In this case Q = 500,

F = 23,

$$\text{by } (a)\ \text{H.P.} = \frac{500 \times 23}{706} = 16{\cdot}28.$$

With a water-wheel we should only obtain

$$\text{by } (b)\ \frac{23 \times 500}{802} = \frac{11{,}500}{802} = 14{\cdot}34\ \text{H.P.}$$

Besides the waste of water in a water-wheel the disadvantage of its slow speed is so great that we shall ignore it altogether as being quite unfitted for electrical work when a new plant is to be designed, and shall only deal with turbines.

Pipes.

When the fall is more than 10 or 12ft., the water is usually conveyed to the turbine in cast or wrought-iron pipes.

When there is a considerable length of pipes they should be kept as small as possible to reduce the cost of the installation. If, however, they are made too small, it takes a considerable portion of the head to overcome the friction of the water flowing through them at a high speed; and if the pipes become furred in the course of a few years they will not deliver enough water, and the turbine will give proportionally less power. This, of course, is not the fault of the turbine, but of the pipes.

The accompanying table shows what various sized pipes will deliver with a loss of 9in. of head per 100ft. of pipe; the velocity of water in feet per second in each case; the initial loss of head in producing this velocity; and the weight per yard of pipes suitable for falls up to 200ft. The loss of 9in. in 100ft. may be more than can be spared for large pipes with low falls, but the figures given will serve as an approximate guide:—

Flow of Water in Pipes.

Diameter of pipe in inches.	Cubic feet per minute.	Velocity of water in feet per second.	Loss of head in producing velocity.	Weight of pipe per yard.		
				cwt.	qr.	lb.
5	23	2·9	·13	0	2	14
6	37	3·2	·16	0	3	5
7	55	3·5	·19	0	3	24
8	79	3·75	·22	1	0	14
9	106	4·0	·25	1	1	9
10	139	4·25	·28	1	2	12
12	218	4·7	·35	2	0	0
14	325	5·1	·40	2	2	0
15	386	5·3	·44	2	3	2
16	454	5·5	·48	3	0	9
18	615	5·8	·53	3	3	15
20	810	6·0	·56	4	1	0
24	1,280	6·8	·72	6	1	0
27	1,770	7·3	·83	7	0	0
30	2,270	7·75	·94	8	0	0

Let us take an example:—200 cubic feet of water has to be conveyed 120yds. What sized pipe should be used, and what will be the total loss of fall? From our table we see that a 12in. pipe will be suitable, and that the loss in friction at 9in. per 100ft. will be $\frac{9 \times 360}{12 \times 100} = 3{\cdot}24$ft.

To this must be added ·28ft., the fall necessary to give the water a velocity of 4·7ft. per second. The total loss will therefore be 3·24 + ·28 = 3·52ft.

N.B.—In working out the horse-power available it is always necessary to take the *nett* fall.

(To be continued.)

SAFETY FUSES.

BY CLARENCE P. FELDMANN.

Immediately after sending you my article on Safety Fuses* I at last succeeded in getting Vol. VIII. of the *Centralblatt für Electrotechnik*, where the experimental results of A. Reinisch† and M. Grassot‡ are reviewed by Herr F. Uppenborn.§

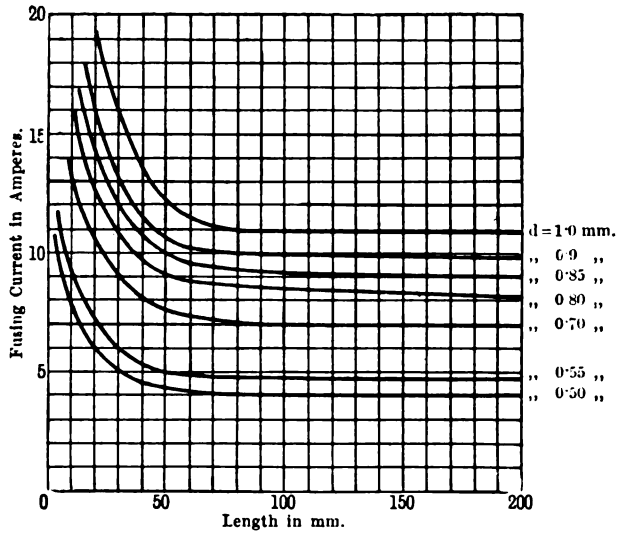
The following Table contains the values of the fusing current which Reinisch observed for lead wires of 2mm. diameter, together with values calculated from the empirical relation

$$C^2 \sqrt{l} = 15{,}250 = 1{,}906\, d^3 \ (d \text{ in mm.}). \quad . \quad . \quad (1)$$

Currents necessary to fuse lead wires of 2mm. diameter and l mm. length.

	Observed by Reinisch.	Calculated from (1).
l = 10mm.	87·35	69·5
20 ,,	66·84	58·5
30 ,,	56·80	52·7
40 ,,	50·01	49·0
50 ,,	46·91	46·4
60 ,,	43·60	44·4
70 ,,	41·24	42·6
80 ,,	40·01	41·2
90 ,,	39·38	40·1
100 ,,	38·74	39·0

The calculated values are very much lower than the observed ones for lengths less than l = 25mm. or so, but certainly for the rest of the table the observed and calculated values agree sufficiently well. Reinisch himself wanted to prove Joule's law



Grassot's experiments.

by his measurements, and concluded that the product $C^2 l$ ought to be constant, but in 1886 already Uppenborn pointed out that, firstly, from Reinisch's experiments $C^2 l$ was not constant, and, secondly, that these experiments only showed the cooling influence of the terminals, and that they were no proof for or against Joule's law. The terminals which Reinisch used must have been rather massive, as is shown by the formula

$$C^2 \sqrt{l} = 1{,}906\, d^3,$$

which gives

$C = 12{\cdot}44\, d^{\frac{3}{2}}$ for l = 150mm and d measured in mms. (1ª)

against Mr. Preece's value

$C = 10{\cdot}77\, d^{\frac{3}{2}}$ for l = 150mm. and d measured in mms. (2).

whilst for l = 150mm. and the different diameters of lead wires which Grassot tested, the fusing current would come out very nearly coincident with Mr. Preece's value, namely,

$$C = 10{\cdot}4\, d^{\frac{3}{2}}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3ª)$$

* See *The Electrician*, May 27, p. 87.
† *Zeitschrift für Electrotechnik*, Vol. I., p. 243 (1883).
‡ *L'Electricien*, Vol. X., p. 420 (1886).
§ *Centralblatt für Electrotechnik*, Vol. VIII., p. 421 (1886).

Digitized by Google

being a special value for $l = 150$mm. of the empirical relation

$$C^2\sqrt{l} = 1{,}267\ d^3 \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Grassot's results are laid down in curves very much resembling the first series of curves in my article. From these curves I took the following "observed" values, and placed them together with those calculated from the following empirical formulæ—

For $d = 0{\cdot}5$0mm.	$C^2\sqrt{l} =$	155, or	$C^2\sqrt{l} = 1{,}240\ d^3$	(d in mm.)
$= 0{\cdot}55$,,	,, =	208	,, $= 1{,}250\ d^3$	,,
$= 0{\cdot}70$,,	,, =	446	,, $= 1{,}300\ d^3$	,,
$= 0{\cdot}80$,,	,, =	660	,, $= 1{,}290\ d^3$	,,
$= 0{\cdot}85$,,	,, =	784	,, $= 1{,}275\ d^3$	,,
$= 0{\cdot}9$,,	,, =	918	,, $= 1{,}260\ d^3$	,,
$= 1{\cdot}0$,,	,, =	1257	,, $= 1{,}257\ d^3$	,,
	Mean value of $C^2\sqrt{l} = 1{,}267\ d^3$			,,

Currents necessary to fuse lead wires of d mm. diameter and l mm. length, as observed by M. Grassot, and calculated from formula (3).

l in mms.	$d = 0{\cdot}5$mm		0·55mm.		0·70mm.		0·80mm.		0·85mm.		0·90mm.		1·0mm.	
	$C^2\sqrt{l} = 155$.		$C^2\sqrt{l} = 208$.		$C^2\sqrt{l} = 446$.		$C^2\sqrt{l} = 660$.		$C^2\sqrt{l} = 784$.		$C^2\sqrt{l} = 918$		$C^2\sqrt{l} = 1$

100	4·0	4·0	4·7	4·6	7·0	6·8	8·4	8·1	9·1	8·9	10·0	9·6	11·0	11·0
120	4·0	3·8	4·7	4·4	7·0	6·4	8·3	7·8	9·1	8·4	9·9	9·1	11·0	10·6
140	4·0	3·6	4·7	4·2	7·0	6·2	8·3	7·5	9·0	8·2	9·9	8·8	11·0	10·2
160	4·0	3·5	4·7	4·1	7·0	5·9	8·2	7·2	9·0	7·9	9·9	8·5	10·9	9·8
200	4·0	3·3	4·7	3·8	7·0	5·6	8·1	6·8	9·0	7·5	9·8	8·1	10·9	9·4

The calculated values are somewhat lower than the observed ones for values of l under 20mm. and over 100mm., at which point Grassot, in coincidence with my own experiments, found the curves nearly horizontal—that is, showing no more decrease of fusing current for further increase of length. This is more clearly shown by the accompanying figure, which is a reproduction of Grassot's figure of 1886.

A GLANCE AT SOME ELECTRICAL FEATURES OF LONDON.

To see ourselves as others see us is always a healthy and sometimes even an amusing process. We therefore give below some extracts from an article by Mr. Robert M'A. Lloyd, which appeared in the *Electrical World* of May 21st. Our national modesty forbids the publication of any other than the more or less depreciatory portions of Mr. Lloyd's review of the electrical features of the metropolis.

Americans are very apt to talk as if the commercial history of electricity was being made in this country while the professors and doctors of the old world were still playing with it in their laboratories, and so a glance at the electrical business of London has been a great surprise to those who have crossed the water within the past year. The development of domestic lighting in England has been characterised by strides almost as great as have marked American progress in street railroading; and with this electrical engineering, contracting and the supply business have all enjoyed a considerable boom.

The inhabitants spend so little money for heat that they can afford to waste some on light, and they pay almost twice as much for an incandescent lamp as we do in New York in spite of the fact that the price of coal is about the same in both cities.

I visited most of the central stations and learned from the resident engineer of each that his plant was the most economical of all. First there is the great Deptford station on the south-east edge of London, located there to avoid stoppages from injunctions, which are used promiscuously in the metropolis by citizens who object to smoke or noise. One feature of the Deptford station that I have not seen described before is the method of blowing out the arc at the dynamo switches. These are large manual switches, with a double-pole, 4-foot break. While one attendant opens the switch another stands by with an instrument somewhat resembling a canoe paddle, having a flexible leather blade, and with this clubs out the arc. Returning from Deptford one feels quite at home on looking in at Lincoln's Inn Fields, where there is a large and complete Westinghouse plant, engines, and generators all shipped there direct from Pittsburg and giving perfect satisfaction at 1,000 volts. There are about 20 central stations in London, and almost every one possesses important features peculiar to itself. In this one city electrical engineers seem to be trying every conceivable method of making steam, driving dynamos, and transmitting and distributing electric energy, and I found there a great diversity of opinion as to which methods were giving the best results. The lighting companies do not do any inside wiring or sell any fixtures. They merely put on a tap for your house and leave the rest to the contractor, under the supervision of a consulting engineer. In London the consulting engineer asserts himself in a way that is unheard of in New York—in fact, it did my heart good to see so many people living on one job.

Outside the Deptford station the most interesting electrical sight in London is the City and South London Underground Railway. After all there is nothing wonderful about it as a power exhibition except that it is there, and in a land where so little has been done in electric motors. The absence of ventilation is the most conspicuous feature. Mr. Grindle explained to me that the air was so bad above ground that there could be no object in introducing it below. A little air does go into the elevator cars when they are opened at the top of the shafts, and walks out with the passengers at the bottom; but any one whose windpipe has not been already seasoned by the steam roads underground can do nothing but gasp while in these electric tubes. This road, however, certainly demonstrates that electricity is the stuff for underground rapid transit, and that underground roads with ventilation, which is not a serious problem, are a very satisfactory means of getting through big cities. The electrical equipment of the road seemed to be very good, but I was somewhat surprised to find that the engineers did not know how to run compound wound dynamos in parallel. The power is generated by Edison-Hopkinson dynamos built by Mather and Platt, and while the series coils are evenly divided between the two legs of the magnet, those on one side only are used, and only used when the machines are running singly. When the machines are paralleled the series coils are all short-circuited, and the potential is regulated by rheostats. As a matter of fact it is exceedingly irregular.

The only electric street railway to be seen is that of the East Metropolitan Tramway Company on the Barking-road. It is more interesting to an American as a museum than an exhibition. There are six cars operated with E. P. S. accumulators and Immisch motors, but the road has been equipped in a desultory way, and no two of the motors are alike; all sorts of gears are used, and the whole make-up would be called "junk" in this country. The road is not at all a discreditable one, when we recall some of our first attempts on this side of the ocean.

THE CUTTRISS CARBON RELAY FOR SUBMARINE CABLES.*

BY CHARLES CUTTRISS.

Until within a comparatively recent period telegraphy was the most important branch of electrical engineering; but of late years developments in electric lighting, power and traction have been so marvellous and we have become so accustomed to calculate and think of volts and amperes by the thousands and tens of thousands that the mind has to exert itself somewhat to realise that instruments using only the hundred-thousandth of an ampere for a maximum current and a millionth of an ampere for a minimum current, are in daily use, and that by means of them we annihilate time and link together the Old and New Worlds. Nevertheless, this is a fact; and by means of these minute currents communication at the rate of twenty-five words per minute is steadily maintained over the Atlantic cables for hours at a time. That this may be done it has become necessary to abandon to a great extent the old system of manual transmission, and to adopt an automatic mechanical transmitter, so that we can now insure the same perfection as regards the shape of the signals and the required spaces at the end of a twelve or twenty-four hours' run as we had at the start.

A few years ago the public were content to send a message to London and get an answer within an hour; now they can get it in a minute or two; but still the cry is for quicker communication.

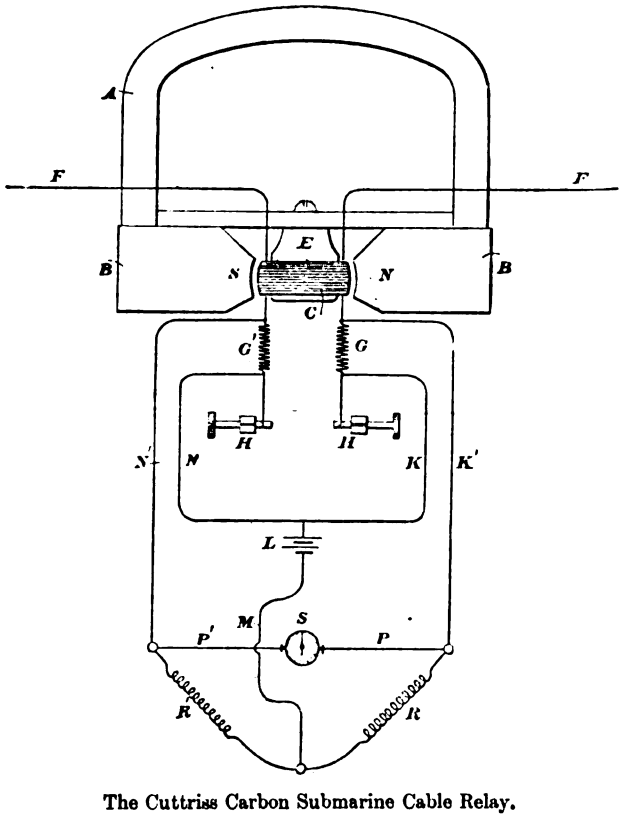
* From the *Electrical Engineer* of New York.

Digitized by Google

As the adoption of the automatic system of transmission has increased the carrying capacity and speed of long cables to the utmost, we can only hope for still more rapid communication between terminal stations by saving the time now lost in the necessary re-transmission of messages at intermediate stations. This, of course, can be done by interposing a relay which shall automatically repeat into the second cable the signals which come over the first one. As all signals over a submarine cable of any length are of an undulatory character, it becomes necessary that this relay should repeat these undulations into a local circuit as faithfully as a telephonic receiver reproduces the undulations of the diaphragm of its transmitter.

After many failures to attain this end during the last ten years, the instrument shown diagrammatically in the accompanying engraving has been invented by the writer. By its means the connecting in series of a number of short cables of about 800 to 1,000 miles in length, or the connecting of a short cable to a long one is perfectly feasible. Up to the present time a relay known as the Allen and Brown has been practically the only one that would work Morse over cables 500 miles long, and with cables of this length the utmost delicacy of adjustment was necessary to obtain satisfactory signals.

Heretofore there has been no instrument which would repeat recorder signals into a local circuit, thereby making it possible to have several offices in a city working directly on to a through



The Cuttriss Carbon Submarine Cable Relay.

cable after the manner in which Morse instruments at various offices work on to one trunk line. In the spring of 1889 I first obtained reliable recorder signals in a local circuit by means of a repeating relay in circuit with the Commercial Cable Company's Canso-New York cable, the copper resistance of which is 13,600 ohms, with an electrostatic capacity of 233 microfarads and a length of 855 knots; the cable is duplexed, and a battery power of 30 volts is used for signalling.

The relay was crude, and consisted of a coil of peculiar shape, which carried two small carbon discs, and which moved in a magnetic field; this coil was placed in the cable circuit. Opposite to the two discs were carbon points, which were connected in a local circuit to the receiving instrument, consisting of two ordinary 8-inch horseshoe magnets, between the poles of which a small coil carrying the syphon was pivoted, the syphon dragging over the surface of the paper.

When the operator at the distant station sent signals, to my surprise they were recorded on the receiving instrument perfect in shape and character, and subsequent measurements showed that the power in the local circuit was upwards of fifty times as great as the initial cable current. Since then I have experimented in every way to find the best form of contact points, but have finally rejected points of any shape, as the adjustments had to be too delicate and the points showed a great tendency to stick and burn.

I then turned my attention to making helices of carbon, and found that by substituting them for the adjustable points all the troubles incident to sticking and burning were eliminated, and that they gave a variable circuit that is entirely under the control of the moveable coil. The relay now repeats most minutely all the undulations of the cable currents.

The strength of the currents in the local circuit can be augmented to such a degree that the local instrument requires no delicate parts, and can be adjusted by the operator instead of requiring the services of a skilled mechanician.

As will be seen, N S are the poles of a permanent magnet; E is an iron core situated between them so as to concentrate the lines of magnetic force into two fields in which a coil C is pivoted at the top and bottom. Thus far the instrument is a copy of the syphon recorder; but instead of using metal springs, weights or analogous devices, to bring the coil back to zero after it has been deflected by a signal, I have substituted the carbon helices G G', connected to the coil by fibres or otherwise, and it will be readily seen that any deflection of the coil must open one spiral and close the other.

Normally the circuits, M, R', R, K', N', G, G', N, K, and L are so balanced that there is no difference of potential at the extremities of the wires P and P'; consequently, the local instrument S is unaffected. Should, however, a signal be set through the coil C it will tend to close one of the carbon spirals and open the other, thus throwing the local circuit out of balance, and energising the local instrument S to a degree corresponding with the movements of the coil; the amount of the energy thus developed follows the laws of the Wheatstone bridge.

By varying the resistances in the local circuit and the strength of the battery, we can obtain any desired power in the local instrument, and, if necessary, a number of them can be placed in various offices in a city by means of the circuit P P'.

It was while experimenting with this instrument, and observing the perfect manner in which the weak cable signals were reproduced by these carbon helices, that I was led to try them as a telephonic transmitter, and was not surprised to find their action all that could be desired. The results obtained have already been described in these columns by the writer.*

THE LOSS OF CHARGE IN THE NEGATIVE PLATES OF ACCUMULATORS.†

BY DR. M. KUGEL.

The observations and tests recorded in the following notes were made on behalf of the Accumulator Company of Hagen, Westphalia, and refer to cells manufactured at their works, that is to say, to cells on the Tudor system.

The battery consisted of 60 No. 9A cells; each contained five positive plates, 300mm. × 300mm. The guaranteed capacity was 215 ampere hours when discharged at 66 amperes. The normal charging current was 54 amperes. According to the assertion of the firm who had put down the cells, the battery did not show the full capacity, in spite of having had a long overcharge amounting to nearly 100 hours. A test charge gave the following results.

Soon after the commencement of charging, gas was evolved from the negative element. The volts rose tolerably quickly to 135, *i.e.*, about 2·25 volts per cell. During a continuation of the charge, the volts and the density of the acid remained perfectly constant. As soon as charging was stopped the volts gradually fell. A capacity test gave a very bad result; whilst discharging at 25 amperes the volts fell, after about 40 minutes, to 90.

The behaviour of the battery on open circuit was next investigated. The cells were overcharged for a period of several hours, until their voltage remained constant and equal throughout the cells at 2 25 volts per cell. The charging current was cut off at 9 a.m. The voltage measured at the poles then came out as follows:—

At 9: 0 a.m.	.....	135 volts
,, 10: 0 a.m.	.....	104 ,,
,, 11:25 a.m.	.....	101 ,,
,, 11:35 a.m.	.....	96 ,,
,, 11:45 a.m.	.....	95 ,,
,, 12:15 p.m.	.....	90 ,,
,, 3: 0 p.m.	.....	83 ,,
,, 11:30 a.m.	(next day)	78 ,,

Measurements were also taken at regular intervals of the voltage, acid density, and evolution of gas of the individual cells. Whilst the positive plates behaved quite normally, the evolution of gas at the negatives continued for some time after the cessation of the charging current. After a certain period it was noticed that

Digitized by Google

the production of gas ceased in some of the cells, the voltage in these cells simultaneously showing a gradual falling off, being at that moment from 1·4 to 1·5 volts. The time at which this occurred varied considerably in different cells. In some gas was given off, and the volts remained at 1·8 to 1·9 for 30 or 40 hours after cutting off the charging current, whilst in general eight or 10 hours was the time taken. The evolution of gas did not cease at the same moment throughout a particular cell, a difference of several hours being observed at different plates. The acid density rose in all the elements equally from about 24·8 B to 25·4 B. When a negative plate was taken out of the cell, and placed in pure sulphuric acid, the gas continued to come off as before. When tested it proved to be pure hydrogen.

So far as appearances went the positive plates were quite normal. The negatives, however, did not present the ordinary metallic grey colour, but appeared whiter, as if sulphated. At the end of the charge metallic grey spots could be clearly seen in the active mass, but after the gas was given off they appeared white again.

The battery was then again fully charged and further tested, current being this time taken out of it. It behaved exactly as before, except that the volts fell off more quickly. Gas began to be given off at exactly the same instant as the volts fell away. The latter took place extremely rapidly, only five to eight seconds being taken whilst falling from 1·8 volts to 0. The pressure remained constant at zero from this point all the time that current was passing through the cell.

The plates in a discharged cell were then replaced by new ones. The cell was then charged and found to have the normal capacity. After stopping the charge the new plates gave off some gas, but not nearly so much as the others. A discharged cell was then filled with chemically pure acid. It behaved exactly as before, the capacity remaining very low. A good cell from another battery was then filled with the acid taken from a bad cell. The negative plates gave off gas after charging, and the capacity which had previously been 177 ampere hours was found to be only 32 ampere hours.

The explanation of the above results is as follows:—The formation of hydrogen at the negative electrodes clearly depends upon an oxidisation of the reduced lead sponge. The reason for this abnormal action is obviously to be sought for in the properties of the sulphuric acid used. Qualitative analysis of about 5 litres of this showed the existence of impurities, consisting of chlorine, nitric acid, arsenic and copper, though only in very small quantities. It is further clear that slight admixtures of other acids cannot cause the excessive oxidisation of the lead sponge, and that the bad effects of the sulphuric acid must therefore be attributed to the metallic impurities. It is well known that metals are far more easily oxidised when impure than when pure. Chemically pure zinc, for instance, is only very slowly dissolved in sulphuric acid. If, however, traces of platinum are present, the action goes on very rapidly, as a local current is set up between the two metals which separates hydrogen at the platinum, and oxygen at the zinc.

It was further shown, by chemical analysis, that the electro-negative metals existing in the acid (*i.e.*, copper and arsenic) after charging were to be found in the lead sponge of the negative plates, whilst the liquid itself was free from them. This conclusion was borne out by the observation that good negative plates of normal capacity in pure acid, when once the deleterious metal had been precipitated on them could not be improved by being placed again in chemically pure acid; and the circumstance that the charged negative plates when placed in pure acid continued to evolve gas, shows that the cause of the evolution of gas had been transferred from the acid to the plates by charging.

The above observations enable us very simply to account for the observed results. The electro-negative metals in the acid at the commencement of the charge are precipitated upon the negative plates. They there set up local currents which liberate hydrogen at the electro-negative metal, and oxygen at the adjacent lead sponge. Of the two gases the latter oxidises the lead, whilst the former is given off. The local current being due solely to the contact between the two different metals is affected very little by the direction which the current through the cell takes. As soon as part of the spongy lead is reduced at the commencement of the charge, the local current causes it to be oxidised again, so that the evolution of gas at the negative plate commences much sooner than usual. A complete reduction of the active mass in the negative plate is, moreover, rendered impossible, and the voltage of the battery remains low, in spite of continuing the charge for an excessive length of time. Stopping the charge has no effect on the local current, and consequently cannot influence the evolution of gas. Discharging the element only influences the fall of volts, in so far as that the sponge is oxidised by the discharging current as well as by the local action. The volts fall more quickly, and gas is given off sooner.

It need hardly be mentioned that no change in the capacity in the proper sense of the word really takes place. The effect of the local current is the same as if a shunt circuit existed inside the cell, the energy expended in which is not reckoned in determining the working capacity. The strength of the local currents may be pretty easily arrived at by measuring the volume of gas given off in a specified time.

CAMBRIDGE UNIVERSITY MECHANICAL SCIENCES TRIPOS.*

REPORT OF THE SYNDICATE APPOINTED TO TAKE INTO CONSIDERATION THE ESTABLISHMENT OF AN HONOURS EXAMINATION IN MECHANICAL SCIENCE.

The Syndicate appointed "to take into consideration the establishment of an Honours Examination in Mechanical Science" report to the Senate as follows:—

The present Syndicate were appointed in consequence of a recommendation contained in the final Report of the recent Mechanical Workshops Inquiry Syndicate. It was there stated:—"The Syndicate are fully aware that the arrangements for the education of the students attending the mechanical department cannot be regarded as satisfactory or complete until provision is made for an honours examination in the subjects taught in the department. At present the only examination in these subjects is the special examination in mechanism and applied science, based on a curriculum wholly inadequate for the more able students of the mechanical sciences." And further, "They are unanimously of opinion that the establishment of an honours examination specially adapted to the scientific training of students in the mechanical department is of urgent importance to the proper development of the study of the mechanical sciences in the University." In these expressions of opinion the present Syndicate fully concur. They have had under consideration (1) the course of study which may appropriately be followed at the University by students who wish to lay a scientific foundation for a knowledge of engineering; (2) the opportunities of instruction which the University offers, by lectures and laboratories, to students of such a course; and (3) the character of the examinations in mechanical science which are held in other Universities. They consider that the wants of students of the mechanical sciences are not met by any of the existing triposes. They consider further that until the subjects of its teaching are embraced in an honours examination the department of mechanism and applied mechanics must have its usefulness much restricted, and they are aware that the want of such an examination deters men from coming to Cambridge who would otherwise be likely to profit by the training in science which the University offers. The Syndicate are of opinion that a curriculum of study in the mechanical sciences, the teaching for which is in the main already provided for in the University, affords proper subject matter for a tripos examination, and they propose that a mechanical sciences tripos be instituted. The Syndicate are of opinion that the general regulations affecting the standing of candidates for the mechanical sciences tripos should be similar to those at present in force for the mathematical and various other triposes.

The Syndicate therefore recommend that the mechanical sciences tripos examination shall consist of two parts, the class list for each being published separately. The first part of the examination shall comprise six comparatively elementary Papers of three hours each on the following six subjects:—(1) Mathematics, (2) Mechanics, (3) Strength of Materials and Theory of Structures, (4) Principles of Mechanism, (5) Heat and Heat Engines, (6) Electricity and Magnetism; together with oral and practical examinations in the following six subjects:—(1) Mechanics and Elasticity, (2) Heat and Heat Engines, (3) Mechanism, (4) Surveying, (5) Drawing, (6) Electricity and Magnetism. The second part of the examination shall comprise two more advanced Papers of three hours each on each of the following four subjects:—(1) Theory of Structures, (2) Heat Engines and Dynamics of Machines, (3) Hydraulics and Geodesy, (4) Electricity and Magnetism; together with oral and practical examinations in (1) Engineering Laboratory Work, (2) Geometrical Drawing and Graphic Statics, (3) Machine Drawing and Design, (4) Applied Electricity.

In the first part of the examination a candidate may present himself for examination in all of the subjects, but he is not expected to take more than five of the written and five of the practical subjects. In the second part of the examination a candidate may present himself for examination in all the subjects, but he is not expected to take more than two of the written and three of the practical subjects. The names of the candidates who pass either part of the examination with credit shall be placed in three classes; the names of those in each class shall be arranged in alphabetical order.

* Abstract from the *Cambridge University Reporter*.

Schedules Defining the Subjects of the Examination (Part I.).—

Schedule I.

1. In Mathematics the subjects of examination will be :—Trigonometrical solution of plane triangles. Simpler geometrical properties of conic sections. The rudiments of analytical geometry, including equations to the conic sections referred to their principal axes. Fundamental ideas of the differential and integral calculus : differentiation and integration of simple functions : geometrical interpretation of differentiation and integration : elementary applications to plane curves, maxima and minima of functions of one variable, areas, volumes, centres of mass, moments of inertia : simple differential equations.

2. The Paper on "Mechanics" will consist of questions of an elementary character on statics, hydrostatics, and kinematics, together with the simple parts of the dynamics of a particle and of a rigid body, the elementary treatment of distributed forces and the rudiments of hydrokinetics. Candidates will be expected to be acquainted with methods of measuring mechanical quantities and with the use of graphic processes in the solution of problems.

3. The Paper on "The Strength of Materials and Theory of Structures" will deal with the preparation and properties of the chief materials used in engineering construction, the kinds of stress to which materials are subjected in practice and the provision of strength which should be made in design, methods of testing materials for strength and elasticity, the various moduluses of elasticity, the determination of the stresses in the parts of structures, the elementary theory of the strength and elasticity of pieces subjected to stress, with applications to such structures as beams, shafts, boilers, roofs, and bridges.

4. The Paper on "The Principles of Mechanism" will deal with the application of the principles of kinematics and dynamics to mechanism, the analysis of mechanism, the theory of mechanism as a means of transmitting and modifying motion, and the characteristics of the more common mechanical contrivances, the use and efficiency of mechanism in transmitting power, the influence and applications of friction, the theory and methods of governing, the balancing of running parts, and other problems in the kinetics of machines.

5. In the Paper on "Heat and Heat Engines," candidates will be expected to show a general knowledge of the character and effects of heat and the elements of thermo-dynamics, and to be acquainted with elementary applications of thermo-dynamic principles to steam engines and other heat engines. The Paper will also deal with the properties of steam and its action in steam engines, the testing of steam engines, their general construction and typical forms, the combustion of fuel, the construction and action of furnaces, boilers and other appurtenances of engines, the supply of steam to engines, including problems relating to valves, the theory and general construction of other forms of heat engines, such as air-engines and gas-engines.

6. In the Paper on "Electricity and Magnetism," candidates will be expected to show acquaintance with the fundamental parts of the subject, with the methods used in electrical and magnetic measurements, with the apparatus commonly used in the industrial applications of electricity, and with the application of general principles to the discussion of practical problems.

Schedule II. (Practical Examinations).

1. Measurements of mechanical quantities ; friction ; tests of material for strength ; measurement of moduluses of elasticity. 2. Experiments on heat ; tests of heat engines ; measurements of efficiency ; hydraulic experiments. 3. Surveying ; adjustment of instruments ; field operations in surveying, levelling, and setting out ; drawing plans ; estimating areas and volumes. 4. Mechanism ; methods of mechanical construction ; marking out work ; adjustment and use of tools, including the commoner machine tools ; construction of surface plates and other standard pieces ; adjustment of the working parts of engines and other machines. 5. Mechanical drawing, including the drawing of machines from measurement, practical geometry, and the use of graphic methods in the solution of engineering problems. 6. Practical electricity, including electrical and magnetic measurement.

In an appendix, the subjects of examination are given in detail, The following section relates to electricity and magnetism :—

Electricity.—Fundamental laws and principles of electricity and magnetism, with special reference to practical applications ; electro-magnetic system of units ; practical units ; methods of measuring electrical quantities ; magnetic measurements ; magnetic qualities of iron ; the magnetic circuit ; batteries ; storage batteries ; dynamos ; characteristics of dynamos ; types of dynamos for direct and alternate currents ; methods of testing efficiency ; alternate currents ; self-induction and mutual induction ; transformers ; electric transmission of power ; motors ; methods of distributing electricity for lighting and other purposes ; electric meters ; electric lamps ; general methods of telegraphy ; testing of land lines and submarine cables ; telephones.

Subjects of oral and practical examination :—

I. Mechanics and elasticity ; measurement of mechanical quantities ; quantitative experiments in mechanics ; friction ; tests of strength of materials ; use of testing machines ; measurement of moduluses of elasticity ; tests of beams, struts, shafts, &c.

II. Heat and heat engines ; quantitative experiments in heat ; use of the indicator ; tests of steam engine and gas engine ; hydraulic experiments.

III. Surveying ; adjustments of theodolite, level, sextant, &c. ; field operations in surveying, levelling, and setting out ; finding the meridian ; plotting plans and sections ; determination of areas and volumes.

IV. Mechanism ; methods of mechanical construction ; marking out work ; adjustment and use of tools, including the commoner machine tools ; construction of surface plates and other standard pieces ; adjustment of the working parts of engines and other machines.

V. Mechanical drawing, including the drawing of machines from measurement, practical geometry, and the use of graphic methods in the solution of engineering problems.

VI. Practical electricity, including electrical and magnetic measurement.

The report is dated May 23, 1892, and is signed by the following :—John Peile (Vice-Chancellor), J. J. Thomson, J. A. Ewing, P. T. Main, Osborne Reynolds, Horace Darwin, W. L. Mollison, R. T. Glazebrook, W. N. Shaw, J. Larmor, H. F. Newall.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—THURSDAY, JUNE 2ND.

Select Committee on the Electric Railway Schemes.

At the sitting of Sir John Kennaway's Committee on Thursday, last week, a discussion arose as to the possibility of any of the Bills getting through all their stages in the present Parliament. Mr. Littler, Q.C., expressed the opinion that the prospects of the Bills behind the Baker-street and Waterloo scheme were altogether hopeless, as even though they were passed by the Committee, they could not get up to the House of Lords in time to be passed this Session. No doubt, however, the same course would be followed on this as on previous occasions, viz., that the Bills would be brought up again at the same stage at which they were left this year, and, therefore, no damage would be done to anybody, except to the members of the Parliamentary Bar, who would be compelled to take a holiday in consequence of the Dissolution.

Sir MYLES FENTON was then examined against the Bill and in support of the case of the South-Eastern Railway Company, stating that the proposed line would interfere with the contemplated extensions of the South-Eastern Company, and with the prospect of carrying out the projected junctions of the South-Eastern Company and the lines north of London. Beneath the station at Charing Cross on the Craven-street property they proposed to establish a depôt for the delivery of vegetables and fruit for conveyance to Covent-garden, the nearest point to which they now conveyed it being London Bridge. There was also a large Continental parcels traffic for the West End, for which they required special accommodation.

Mr. F. BRADY, the engineer to the South-Eastern Company, and Mr. WOLFE BARRY also gave evidence as to the interference with the South-Eastern Company's property and other engineering details, and in cross-examination the latter gentleman said that electrical locomotion had no doubt reached a high state of perfection and excellence, but it could not be pretended that at present it was able to compete with steam. There was no doubt the time was coming when electrical railways would be more generally used ; but with reference to the proposed line what was wanted was a line by which they could run through trains right from the north of England to Dover.

Mr. EDWARD RYDE, surveyor, having given evidence as to the value of the Craven-street property to the South-Eastern Company,

Sir F. BRAMWELL, consulting engineer to the South-Eastern, said that the carrying out of the Baker-street line would be a serious hindrance to a railway going north and south, which would carry ordinary carriages and engines. Although, no doubt, the proposed line would get some amount of traffic which might or might not—he thought it would not—pay for its construction, whatever it got would be traffic taken away from a railway line which must be provided, and the sanctioning of this line would entitle them to raise a Parliamentary opposition to the scheme of the South-Eastern Company. He did not like to joke before a Committee, but it really looked like "pure cussedness" for the promoters to put the Charing Cross Station where they proposed.

Mr. PEMBER: Does your objection apply to all electrical railways?

The WITNESS: It is not an objection to electrical railways at all. If they would make the line 16ft. 2in. wide they would be able to take ordinary rolling stock along it. He believed in electricity as a source of traction on railways ; it might not be so economical as steam at present, but it might become so hereafter.

Sir BENJAMIN BAKER also gave evidence against the Bill in regard to its interference with the Metropolitan line at Baker-street, and said that he confined his objections to the Bill on that ground only. He was an electrical man himself.

Mr. PEMBER: I know you are ; that is why I am so sorry to see you where you are. As far as the scheme goes for fulfilling what it affects to fulfil you have nothing to say against it.

The WITNESS: I have nothing to say against it except that it interferes structurally with the Baker-street Station.

Mr. SEATON, engineer to the Metropolitan Railway Company, and Mr. BELL, general manager of the Metropolitan, also gave evidence against the Bill ; and the Committee then adjourned, the evidence having been concluded.

FRIDAY, JUNE 3RD.

Mr. LITTLER addressed the Committee on behalf of the South-Eastern and Metropolitan Railway Companies, quoting statistics and calculations to show that the Baker-street-Waterloo line would not be likely to pay, and urging that the evidence had substantiated that so much damage would be caused to existing interests that it ought not to be passed. He was quite sure, he said, that his friend, Mr. Pember, would not be willing to sink his fees in an "elongated pipe" of that description. The scheme was full of doubts and full of experiments, and it would have the effect of going dead against one of the main recommendations of the Joint

Digitized by Google

Committee, which said that no line should be sanctioned which would delay the construction of a through line. The scheme, he contended, was marked with every conceivable defect; it had no recommendations on the evidence that had been given, and the only thing that the promoters had to rely upon was the instinctive feeling that it would be a good thing to reduce the numerous omnibuses which passed along the streets, and which everyone who knew the traffic of London would feel to be a desirable thing. Speaking further on behalf of the Thames Conservancy, he pointed out that the Conservators had vested in them certain rights of foreshore which were in dispute between the Crown and the citizens of London; and as the crown of the tunnel would come within six feet of the bed of the river, it would be a considerable interference with their rights, though he did not mean to say that there would be danger from the proposal. They had no power to prevent any works in the waterway, or in the soil beneath, but he asked that a special clause might be given them which would entitle them to such compensation as was represented by the value that the privilege of passing under the Thames would be to the Company instead of the bare value of the soil to the Thames Conservators, which was all that by the common law they would be entitled to.

Mr. FREEMAN then proposed to speak on behalf of the hotels in Northumberland Avenue.

The CHAIRMAN: I thought they were all settled with.

Mr. PEMBER: So they are. It is a positive fact that there is only one word in the clause that is open to objection.

Mr. FREEMAN, however, continued his address, asking that if the line were passed by the Committee, a special protective clause should be given to them on account of the exceedingly difficult and treacherous nature of the soil, the massive buildings in Northumberland Avenue being actually built over the bed of an old stream. In the case of the Victoria Hotel, a sum of over £80,000 had to be expended before any foundations were got in at all.

Mr. PEMBER then replied on the case, and pointed out that the financial prospects of the line were not of that questionable nature which the opponents had sought to make out. If they only carried the 5½ millions of passengers per mile as the Metropolitan Railway Company did in 1867, that would represent a traffic of 15 millions, and with that at an average fare of 2d., or anything like it, it would pay over and over again. To do that they would only need to run 120 trains each way, or 240 trains per day, half-full on the average, which would mean only a nine-minute service. The traffic which went by the existing omnibuses from Charing Cross to Baker-street amply justified them in expecting that at least that traffic would be realised, in addition to which there would be the thousands that came in each day to Waterloo, and to whom the line would prove of especial advantage. Replying to the strictures upon the success of the City and South London line, he said that line carried six million passengers, notwithstanding that it was very poorly equipped with rolling stock. Compared with the present scheme it was very small and inadequate, the tunnel being only 10ft. in diameter, as against 12ft. on the Baker-street line, which would make all the difference in the comfort to the passengers. In fact, with smaller wheels, the line would be able to take a Pullman car, and for low speeds large wheels were not required, they being wanted only for high speeds of 50 or 60 miles an hour on the great through lines. In conclusion, in view of the opposition of the other railways which had contemplated a line across London for so many years, but who had done nothing to realise it, he said the question for the Committee to decide was "Is London to stand still?"

The Committee consulted for some time in private, and on the readmission of the public into the room,

The CHAIRMAN said the Committee were of opinion that the preamble of the Bill was proved. They would give to the Victoria Hotel a special clause of protection similar to that given in the case of the Central London line to the Equitable Insurance Office. In regard to the land sought to be taken from the South-Eastern Company at Charing Cross, if the South-Eastern Company wished to clear up a point which had been raised as to interference with a proposed subway they would reserve their decision until they had heard further engineering evidence. As to the question raised by the Conservators of the Thames, that was a matter of clauses.

Mr. FREEMAN asked that the protective clause should be given to the Grand and Metropole Hotels, which he also represented, which was acceded to.

The Committee then went through the clauses of the Bill, the South-Eastern and Metropolitan Companies having retired from the discussion, reserving their right to oppose the Bill in the House of Lords. After argument, the Committee declined to give the special clause asked for by the Thames Conservators, and finally ordered the Bill to be reported to the House.

The Committee then adjourned till Thursday, June 9th, when they proposed to proceed with the Great Northern and City Railway and the other Bills in the group.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 21, 1892.

The American Institute of Electrical Engineers.—The American Institute of Electrical Engineers met for its annual election of officers on Tuesday last. The report of the Council showed that the total membership has increased to 615, a net increase of 74 for the year. The election resulted in the election of Mr. Frank J. Sprague as president, and for vice-presidents Messrs. A. E. Kennelly, Nikola Tesla, and O. T. Crosby, in addition to the three who held over from last year, namely, Messrs. T. D. Lockwood, Carl Hering, and W. J. Hammer. The choice of Mr. Sprague for president was made unanimous, and although but a small part of the total membership were present to cast their votes, his election will, doubtless, give general satisfaction. Since the organisation of the Institute in 1884, nearly every branch of the electrical industries has been represented in the presidential chair by some one prominent worker, with the exception of the electric railway industry. The telegraph has been represented by Mr. Norvin Green, journalism by Mr. T. C. Martin, educational interests by Prof. Wm. A. Antony, electric light by Prof. Elihu Thomson, and the telephone by Mr. Alexander Graham Bell. At the meeting of the Council just before the election three honorary members were elected, these were Lord Kelvin, Herr Werner Siemens, and Mr. Cyrus W. Field. At the dinner, which took place in the evening, a number of speeches were made by representatives of the different branches of the electrical business. Prof. Geo. Forbes, of London, was present, and made a speech, in which he drew comparisons between the American and foreign methods and progress. He was very outspoken in his opinion that in the matter of electric lighting London was now far ahead of American cities, although in some other respects, especially in electric railroading, the Americans were far in advance of the English and Continental practice.

The Westinghouse Company.—The first annual meeting of the Westinghouse Company since the reorganisation was held at Pittsburg this week (Wednesday). The old Board of Directors, with one exception, was re-elected, an indication that the former policy of the Company will be continued. The report of the president shows that bills payable March 1, 1892, were $461,962, and the accounts payable at the sum of $266,973. The total sales of the Company in the field of electric lighting and power for the period from Jan. 1, 1891, to March 1, 1892, aggregated $3,468,900. Orders taken during March and April of this year amount to $1,576,000. The report showed that the indebtedness had been reduced from $5,398,000 in January of last year, to $1,885,000 in March of this year. The make-up of the Board of Directors shows that in this Company, as in the new General Electric Company, the management is largely in the hands of capitalists and financiers; and it is the general opinion that it would not be safe to make any prediction as to the possibility or impossibility of a combination between the Westinghouse and the General Electric Company during the present year; it should be said, however, that rumours to this effect are persistently denied by officials of both companies, who are in a position to know the actual state of affairs.

NEW YORK, *May* 27, 1892.

The Proposed Chicago—St. Louis Electric Railway.—The proposition to construct a high-speed electric railway between Chicago and St. Louis, upon which express trains drawn by electric locomotives would be run at the maximum speed of 100 miles an hour, has been to a considerable extent regarded as more or less visionary; but the idea is really beginning to assume a somewhat substantial shape. Dr. Wellington Adams, who is at the back of this bold project, has been quietly at work developing his plans and placing the whole affair on a substantial business basis. The entire route has been surveyed, and a line 248 miles in length between the two cities has been laid out, without the necessity of introducing a single curve, and without encountering anything more severe than a 2 per cent. grade. The estimate for the construction of the entire line is now placed at $7,000,000, and it is intended to begin the grading of the line in Christian county in Central Illinois during the month of June. According to the present plans, two power stations only will be built, each of at least 10,000 H.P. capacity, one of them being located close to the mouth of a coal pit containing an almost unlimited supply of fuel, while the other is as favourably situated in close proximity to an extensive water-power plant. These two stations will be located midway between the centre and the extremities of the line, so that from each station will be transmitted the power

Digitized by Google

for one-quarter of the line in each direction. It is highly probable that some form of three-phase motor will be employed, and that the potential on the primary mains will be at least 25,000 volts, while that on the motor circuit will be probably 2,000 or 3,000 volts. It is authoritatively stated that the right of way has been obtained for fully 60 per cent. of the line, that property has been secured for the power stations, and that terminal facilities have already been secured in both Chicago and St. Louis. It will be of interest to Englishmen to know that two prominent English electrical engineers have been consulted in drawing up the plans for this bold undertaking, and that they are deeply interested in its progress. Whatever may be the outcome of this pioneer effort at high-speed long-distance passenger traffic by electric motors, the scheme is certainly one which has attracted and still engages the attention of the American public in a very striking and characteristic fashion.

CORRESPONDENCE.

NEWCASTLE CENTRAL STATION COSTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Jackson has been a pioneer in more ways than one, and we should be—I know several who are—cordially thankful to him for his frankness in submitting the station data for the last year to public criticism, as well as to fill notebooks in which such information will be found very useful. There are, however, one or two points to which, if you can spare me the space, I should like to draw attention, and, should Mr. Jackson deign to notice this letter, be glad to have his answer. Leaving outside the question of correctness or otherwise of his system of measuring alternating electrical energy, there appears on page 107 of your issue of June 3rd, some figures as to capital cost, which I take it were given at the discussion on the Paper before the Institution. There it is stated that the capital cost per lamp installed equals 30s. Now in the Paper under the heading of "capital" it is stated that the cost per kilowatt will be £50. Taking 50 watts lamps, that is $\frac{1000}{50} \times \frac{1}{50}$ £ or £2. 10s. per lamp installed; a sovereign more than the figure given in your leaderette. Of course, it may be argued that lamps installed are not lamps supplied; but surely provision must be made for all lamps wired, and in any other case figures are fallacious and unreal. Again, at the end of the Paper, as given in a contemporary (though not curiously enough by you), occurs a sentence, "Also the total cost of the unit sold equals 2·9086d., which includes everything except Directors' fees and *legal charges*."

This figure, however, in the Paper is detailed out, and under the last heading appears:—"General (rent, rates, taxes, *law*, sundry expenses) 0·6807d."

Is this not a discrepancy?

Taking the figure given, however, and looking into the details, we are told that the "cost of the service" amounts to 1·9462d.; but in the summing up, "labour and supervision" appears to be debited only with 0·8163d., whereas all the other items appear as given under their respective headings. If I am not very much astray, the cost per unit sold when corrected by the amount stated will be nearly 4d., and not under 3d.

With regard to the vexed question of alternators running in parallel, there are to-day many engineers of eminence who hold that no published statements are to be found which go to show that any one station having this type of plant is running the units in parallel as an everyday occurrence. Of course it is well known that in various instances it has been done; but even Mr. Wilmhurst, of Exeter, who is, I understand, operating Mordey-Victoria plant, wrote to a contemporary recently and strenuously opposed the practice. Could we not prevail on the respected engineers of the Brush Company to throw some light upon this obscure point, and so help those who often have to press their convictions upon the advocates and users of low-tension and secondary battery plant? So far as the writer is aware, Deptford is the best-known instance of this practice, but being an exceptional case, and it can hardly be cited to back an argument or to support a contention in favour of the alternating system generally.—Yours, &c.,

Liverpool, June 6, 1892. CHARLES H. YEAMAN.

[Our correspondent, in arriving at his figure of £2. 10s., takes a 50-watt lamp as the basis of his calculations. If a 30-watt lamp is substituted, the result will be in accordance with that of Messrs. Heaviside and Jackson. The omission by us of the last paragraph of Messrs. Heaviside and Jackson's paper was due to the fact that the authors had not filled in the important figure referred to, and we were unable to do so ourselves on account of the very discrepancies amongst its component items alluded to by our correspondent. Our efforts to obtain the authentic figure were fruitless.—ED. *E.*]

THE TELEPHONE AND ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was greatly struck when reading your leading article last week with the absurdity of the contention of the telephone companies to possess the exclusive right to employ an earth return.

All telephone companies will shortly be compelled to lay down metallic returns, not only on account of cross-induction from light, power, or telegraph circuits, but also in quite as great a degree by reason of the induction of one earth return telephone circuit on another. It is a well-known fact that much of the disturbance felt on the earth circuits in London is due to cross-induction from other earth circuits belonging to the same company.

That the adoption of the metallic return will entirely obviate all difficulties arising from the induction effects produced by light, power, or telegraph circuits is now beyond question.

In Newcastle, where metallic circuits have been adopted, many of the lines of the telephone company run side by side with post-office wires, and also with electric light wires carrying an alternate current, these latter not being in the shape of a concentric cable. No injurious effect whatever is felt, unless the lines are totally out of balance. The only rational course for the telephone companies to pursue is therefore to convert their earth into metallic circuits as soon as possible, when they will be in a position to hand over the entire proprietorship of the electric cesspool to traction companies without any prejudice to their own interests.—Yours, &c.,

Newcastle-upon-Tyne, June 8, 1892. F. J. MOFFETT.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The Wimborne Rural Sanitary Authority invite tenders for lighting the public streets of the town and special drainage district for three years from October 21st. Particulars and forms of tender may be obtained at the office of Mr. M. Luff, Union Offices, Church-street, Wimborne, where tenders are to be delivered by the 21st inst.

TENDERS ACCEPTED.—The tender of Messrs. Paterson and Cooper to instal the electric light on board the training ship "Shaftesbury" for the sum of £1,068, and that of Messrs. Frazer and Sons to supply the necessary boilers and furnaces for £423, have been accepted by the School Board for London.

——— The Southampton Town Council have accepted the tender of the Newton Electrical Engineering Works, Taunton, to instal the electric light at the Public Baths for £324.

——— The Tayler Smith Electric Lighting Company have accepted the tender of Messrs. Shoolbred and Co. for the execution of certain alterations and additions to 53, South Molton-street, W., the amount of the tender being £728.

——— At a meeting of the Dundee Gas Commission on Friday, tenders for the work in connection with the buildings of the electric lighting station to the extent of £3,112. 10s., and in connection with the electric works to the extent of £17,330, were accepted. It has been decided to start with three Lancashire boilers, two engines of 60 H.P., and four of 130 H.P., each coupled direct with a dynamo and on the same bed-plate. Accumulator batteries will be erected at the station to regulate the supply, and also to do

Digitized by Google

away with night work. Underground cables will be used, and the plant to be laid down will be equal to supply 5,000 sixteen-candle lamps. The price proposed to be charged is 6d. per unit, or about equal to ⅜d. per lamp per hour.

CHISWICK.—The special committee appointed by the Local Board to consider the electric lighting tenders sent in, are of opinion that a new schedule should be prepared, and it is proposed to call in Mr. Spagnoletti to advise them.

PUBLIC WORKS IN BUCHAREST.—H.M.'s Chargé d'Affaires at Bucharest has informed the Secretary of State for Foreign Affairs that it is probable that tenders will shortly be invited for the execution of various public works for the improvement of that town, such as lighting by gas and electricity, erection of new public buildings, establishment of electric tramways, &c. Such further details as are in the possession of Her Majesty's Government may be seen on personal application at the Commercial Department of the Foreign Office between the hours of 11 and 5 daily.

MR. LEOLINE A. EDWARDS.—This gentleman, formerly of the Brush Electrical Engineering Company (Limited) and the Electric Construction Corporation (Limited), has opened an office at 19, Laurence Pountney-lane, Cannon-street, E.C., where he will carry on business as an electrical and mechanical engineer.

LLANDUDNO.—A very complete installation of electric lighting has recently been carried out at the large hydropathic establishment of "Craigside," by Mr. Wm. Kingsland, A.I.E.E. The plant comprises engine, boiler, and three dynamos, and a set of 55 E.P.S. accumulators, K 19 type. There are about 420 incandescent lamps, from 8 to 25 c.p., some arc lights for the grounds, and electromotors for working the machinery in the laundry, hoist, &c.

MINING MACHINERY.—On Saturday last the Federated Institute of Mining Engineers paid a visit to the works of Messrs. W. T. Goolden and Co., 1, Woodfield-road, Harrow-road, with a view of seeing the electric machinery connected with the application of electricity to mining. A large party, among whom was the secretary of the Institution, Mr. Walton Brown, of Newcastle, joined in the visit, and were received at the works by Mr. W. T. Goolden and Mr. Ll. B. Atkinson. Among other objects of interest the party inspected a pumping plant, consisting of a 15 H.P. Goolden mining dynamo; a three-throw ram pump with 5½in. plungers, 9in. stroke, driven by a Goolden mining motor; a coal-cutting plant, including a 50 H.P. dynamo, coal-cutting machines, terminal boxes, portable cable drums, &c., and a 80 H.P. mining dynamo; part of a plant for driving two pumps, one capable of dealing with 400 gallons per minute, on a 450ft. lift, and driving also a colliery ventilating fan; an electric lighting plant, consisting of a 80 H.P. direct-driven Goolden-Willans set; a complete drilling plant for the ironstone mines to Messrs. Bell Bros., Middlesborough (in construction); parts of the plant the firm are now constructing for Messrs. John Watson and Co., of Earnock, comprising two hauling engines, two lighting dynamos, power dynamos, driven by Westinghouse engines, with a total of 120 B.H.P. In the instrument factory the party inspected the latest patterns of instruments now being made, including Evershed's patent shielded voltmeter, which can be used in central stations close to the dynamo without being affected by the same. A good deal of the plant above enumerated was shown in actual operation, and the party left expressing great satisfaction with all they had seen.

THE KIMBERLEY EXHIBITION.—The South African and International Exhibition, which is to be opened at Kimberley in September, is to be lighted entirely with the electric light. For the extensive grounds of the Exhibition, and interior of some of the principal buildings, arc lamps are to be used. These will be worked from three Manchester dynamos, each for an output of 900 volts, 10 amperes; the total number of arc lamps to be used is 37, each of 2,000 c.p. The interior of the smaller buildings will be lighted with incandescent lamps of 16 c.p., worked from three Manchester dynamos, each for an output of 110 volts, 120 amperes. The whole of the plant both for the arc lighting and incandescent lighting is being supplied by Messrs. Mather and Platt (Limited), of the Salford Iron Works, Manchester.

NEW CLASS OF ELECTRIC LAUNCH.—Mr. Sargeant, of Strand-on-the-Green, Chiswick, is now laying down, at the new Electric Launch Works, Eel Pie Island, Twickenham, an electrically-propelled gig, carvel-built, in bright cedar. The boat is designed to give a mean speed of 6½ to 7 miles an hour, with one charge of about 5 to 7 hours' duration. She will be fitted with an awning, cushions, electric light, electric bell forward, gunmetal rowlocks, and sculls, a balance lugsail forward, and a gibheaded mizen aft. The accumulators being sealed and placed below the water-line form ballast and give greater stability, and the boat can be rowed, sailed, or electrically propelled at pleasure. She is being built to the order of F. W. Hagelmann, Esq., of Granby-street, N.W., and will conveniently accommodate six passengers. This class of electric launch will be very useful for the Upper Thames and canals.

NEW TELEPHONE COMPANY (LIMITED).—We are informed that the canvass has reached a successful termination, a large number of subscribers having been obtained.

BOOK CATALOGUE.—Herr Julius Springer, of Berlin, has just issued a very full catalogue of engineering and electrical works published by his house. The catalogue contains no less than 200 pages, and forms one of the most complete lists of electrical and engineering publications we have seen.

VOLUNTARY WINDINGS-UP.—At a meeting of the shareholders of Anders, Elliot and Chetham-Strode (Limited), held on the 31st ult., it was resolved to voluntarily wind up the Company; and Mr. F. H. Ebsworth, chartered accountant, of 1, Arthur-street East, E.C., was appointed liquidator.

——— The shareholders of the Mining and General Electric Lamp Company (Limited) resolved, at a meeting held on May 24th, that as the Company could not, by reason of its liabilities, continue its business, it be voluntarily wound up; and that Mr. J. H. Hays, of 11, Abchurch-lane, E.C., be the liquidator.

GRANGE SYNDICATE (LIMITED).—Under the failure of this Company the usual summary has been issued. The Company was incorporated on August 1, 1890, for the purpose of experimenting upon and developing a patent process for tanning leather by means of electricity, in terms of an agreement made between the Company and Mr. L. A. Groth, of Tokenhouse-buildings. The nominal capital of the Company was £2,000, and the total subscribed capital £1,660. The liabilities to creditors are £581, and the assets are returned at £1. 17s. 11d., the liabilities as regards contributories being £1,550. The first meeting of creditors was held yesterday.

DISSOLUTION OF PARTNERSHIP.—The dissolution of partnership is announced of Messrs. Kipping and Hooton, trading as the Universal Telephone Company, which business has, as we announced in last week's *Electrician*, been taken over by the National Telephone Company (Limited).

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

May 10, 1892.

8,838. A. E. VIDAL. London. Improvements relating to the application of electricity to spring mechanism.

8,854. J. SMALLWOOD. London. Improvements in fittings for electric light.

May 11, 1892.

8,894. A. E. HARDAKER. Liverpool. A type-writing electric telegraph.

8,956. A. KNOX. London. Improvements in or relating to electro-medical belts and appliances.

May 12, 1892.

8,986. D. RYLANDS. Barnsley. Improvements in mains and conduits for electric cables, and in collars and connections for same.

8,987. P. GERMAIN. Paris. Improvements in secondary batteries and accumulators. [Date applied for under Patents Act 1883, Sec. 103, February 23, 1892, being date of application in France.]

9,002. W. MACPHERSON and A. J. HOWES. London. Improvements in connectors and like appliances for electric lighting and kindred purposes.

9,014. H. J. ALLISON. London. Improvements in storage batteries. (P. Kennedy and C. J. Diss, United States).

9,036. R. BRADLEY, N. L. POCOCK and W. BROWN. London. Improvements in electrical accumulators.

9,056. H. S. MCKAY. London. Improvements in means for electrically giving reciprocating motion.

May 13, 1892.

9,105. C. A. BECK and L. KAMM. London. An improved column-printing telegraph for facilitating the receiving and transmission of messages.

9,108. C. P. SHEWSBURY and J. L. DOBELL. London. Improvements in or connected with electric batteries.

9,110. G. A. NUSSBAUM. London. Improvements in microphones or transmitters.

9,132. H. HOWARD. London. Improvements in heating and welding by electricity.

9,136. R. THORNE. London. Improvements in or relating to electric alarms.

9,142. A. L. FYFE. London. Improved combined building block and electric insulation.

Digitized by Google

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

8,009. POORE. Electric call apparatus.
8,874. BENNETT AND HIDES. Telephones and electric bells.
9,048. COGAN and others. Illuminating road vehicles electrically.
10,832. WOODHOUSE AND RAWSON UNITED (LIMITED). (Preschlin.) Electrical transformers.
10,877. VOYSEY. Hauling electric, &c., cables.
11,004. ROSSEAU. Electric accumulators.
11,016. CALLENDAR. Dynamo-electric machines.
11,048. JOHNSON AND PHILLIPS. Electrical mains.
11,060. GIRAUD. Thermo-electric batteries.
22,657. WATTS. Electrical signalling.
7,954. POORE. Electric call apparatus.
10,843. FERRAND. Regulating electric currents.
11,294. BENNETT. Telephonic exchange signalling.
11,313. BOLTON. Utilising electrical energy, &c., in rock boring.
11,560. HARDINGHAM and others. Galvanic batteries.
12,726. THOMPSON (Lahmeyer and Co.). Electrical armatures.
17,849. LEA and others. Electric light fittings.
18,097. SOUTHER. Galvanic batteries.

1892.

3,030. LAKE. (Consolidated Car-heating Company.) Lighting railway vehicles by electricity.
4,578. CASEY. Electric lamps.
4,691. SCHWEIZER. Secondary electric clocks.
4,244. ENDALL. Ships' telegraphs.
6,050. THOMPSON. (Williams.) Electric conductors.
6,083. SMITH. Incandescent electric lamps.

COMPANIES' MEETINGS & REPORTS.

Electric and General Investment Company (Limited).

The third ordinary general meeting of the shareholders of this Company was held yesterday at Winchester House, Old Broad-street, under the presidency of the Duke of Marlborough.

The SECRETARY (Mr. J. Cecil Bull) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN then said: My next duty is to make a statement to you with regard to the condition and prospects of the Company generally. It is always a pleasant task for the Chairman of a Company, when that Company is in a completely flourishing condition; and I am quite sure that no shareholder who has read through the report of your Board can be other than convinced that your Company is in an extremely flourishing condition. Speaking for myself, as the Chairman of your Company, I must disclaim any active part in the prosperity which has fallen to your lot. It is really owing to the exertions of the other Directors at the Board, and to their large experience, as well as their personal ability, that I am able to take the chair on the occasion of your receiving the report in question. Your Company, of course, occupies a position not different from many other Companies in this large centre of commerce and industry. It is essentially a Trust Company or, say, a promoting Company; and although, of course, it is not every industry, however able the Directors may be, that can produce such a balance sheet, yet, at the same time, the character of our business is such that I think the profit we show is perfectly legitimate. I think you will see, too, that it has been gleaned not so much by the peculiar character of our enterprise as by the ability and caution of your Board. It has been owing largely to the indefatigable efforts of this Board that we have been able to carry to a successful issue several important undertakings. I will not go through the whole of these undertakings, but I will mention this in passing that we show in the profit and loss account that there remains, after paying everything, a balance available for distribution of £28,863. Well, now, gentlemen, you have heard of companies of a financial character such as this one earning large profits, but at the same time you have heard of them embarking on very disastrous enterprises; and as there are large profits to be gained in this business, so there are large losses, and it depends on the prudence of the management whether it is loss or profit. There is a great difference between the character of the securities selected for investment, and it has so turned out that our investments have been very prudently selected. It has been the custom of Boards sometimes to be too optimistic, and to rush into investments when on paper they appeared to have great prospects of profit, whereas a little later on difficulty and disappointment have been the result. Your Directors, however, have tried to follow this course—they have never gone into investments which they have not thoroughly investigated, and they have always looked to the disadvantages as well as the advantages offered. So far, their judgment has been shown to have been correct. Many enterprises have been discussed by the Board, and it is really not a great number—I mean, large ones—that have been selected. The City of London Electric Lighting Company has been launched to a large extent—I may say, almost entirely—by your Company. That was a very large enterprise, which promises to have a very great future. It has the privilege of lighting this great city for 40 years. There will be a great demand for this commodity of the electric light, for which I think you will see a large expenditure, for persons in the city are not so economic in regard to the lighting of their places of business as they are of their private residences. The receipts of that Company will, therefore, be, I think, very large, and consequently I feel sure that that Company will prove a great success to investors in it. Then I come to the next matter which has attracted our attention—namely, the Pioneer Telephone Company. You are aware, of course, that the Government have embarked on a new policy with respect to the telephone. They for years, through the Post Office, placed difficulties in the way of the development of the telephone; but the department have seen that the demand for business purposes for this marvellous invention is so large that it is absolutely necessary for it to withdraw its opposing hand, and not only that, but to come forward and lend its assistance in developing the industry. The Bill before Parliament, which, no doubt, will pass before the Session is concluded, is accompanied by a Treasury Minute, under which the Government authorise the Post Office to spend £1,000,000 on the establishment of trunk lines throughout England. That means that the Pioneer Company, which has been launched under the auspices of your Company, will be the means of bringing out the New Telephone Company, which will establish a twin-wire system of telephone, first of all through the Metropolis and then through the large towns of England, so that all persons who want to do their business in future with their correspondents in their own offices—between their own offices in London and offices in the country—will be able, under this new arrangement, to talk with the utmost facility and ease, without any interruption or delay, exactly as if they were sitting in the same office with the persons with whom they were doing business. In a country the size of England—a country so small as England—you can conceive the enormous development of this industry through such facilities as these. We really have as yet never had the opportunity of using this invention; and you can easily conceive, from the facilities I have mentioned, what an enormous development it is capable of. It was in the full contemplation of all these facts, with great discretion, and after considerable care, that your Board embarked on that work, and I may say that you may look forward to that being a very successful venture. That brings me on to show what is the view of this Board, and I feel sure that it will also be the view of all the shareholders in this Company, namely, that it is not simply our business to make a profit and clear out with that profit, leaving these starvelings—as I heard one of my colleagues say—to run about naked in the streets. It will be our business not only to bring these offsprings into the world, but also to see that they have a proper godfather and godmother, and that they prosper as time goes on. The few enterprises of a large character that your Board have had to deal with have been successful, and that they may continue to be so will be the desire of your Board. We want to see that all the enterprises we are instrumental in bringing before the public shall continue to prosper after they have been started, practically, by our acts. I do not know that it would be my province—it is really not my province, as a matter of fact—to go into the balance-sheet, and I shall, therefore, refrain from that task. Other Directors of the Company are far more expert upon the points of the balance-sheet before you than I am. Although I may, to a certain extent, be able to appreciate the merits of the balance-sheet, yet there is a vast difference between being able to appreciate the merits of the balance-sheet and being able to explain it in a lucid manner. I do not think I need take up the time of the meeting with any long remarks of mine upon the past actions of your Board—in fact, upon the results of the past year's working. The report speaks for itself. It is not long, it makes a few statements, and it refers briefly to the reserve fund that has been established. It also states the total amount for distribution, alludes to the amendment of the articles of association, which we recommended, and which you approved, and it also alludes to the fact that Mr. Emile Garcke, who for many years was connected with the Brush Company, and who was instrumental in bringing that Company into the successful position it now occupies, has assumed the position of Managing Director of this Company. That is a fact upon which I think you are to be congratulated. With respect to the future I will only say a few words. I hope we may have before us in the coming year industries that we shall be able to take up and confidently recommend. If so, I have no doubt we shall be able, under the wise guidance of the present Directors, to bring before you as successful a balance-sheet next year as the one we now submit to you for the past year. You must remember that these are very bad times, and that no company hardly at the present time holds a general meeting without the Chairman having to make some apology for there being either no dividend or a low dividend. On this occasion it is my fortunate position to have to make no statement of that sort. You have to look in this Company to one great industry—that is, the future of the electrical industry of this country. It is an entirely new industry—an industry that our fathers had no idea of; that we, perhaps, fifteen years ago hardly realised would become the great business which it will be, and which our sons perhaps will carry to its full development. There is no doubt that this Company, being early in the field, will gain experience and knowledge, so that, as the industry becomes a growing business throughout the whole country, we shall be able to get into our direction what I will call the plums of the business. The City of London Electric Lighting Company is certainly one of the early plums that have been ripening in this enterprise, and I am sure that others will come. It will hardly be my business to lay before you the sort of general schemes which the Board have, and the things they look forward to as likely soon to occupy your attention; but I may tell you, generally, that we anticipate, in the course of next year, several important questions coming before us upon which we shall be able to take an active part, and that the knowledge which has been gained in the past year will enable us to act with prudence, not only in the interests of the shareholders, but, as I said before—and I lay great stress upon it—with respect to the interests of those who will come to us and pay us profits similar to those which we are now paying to you for putting their

Digitized by Google

enterprises on a financial footing. I do not think that I need occupy your time further, and I will, therefore, move :—

"That the Directors' report and statements of accounts to May 31, 1892, with the apportionment of the surplus profit as proposed, be and the same are hereby received and adopted."

Mr. GEORGE HERRING, in seconding the motion, warmly recognised the successful exertions in every way of the Chairman to promote the welfare of the Company. The speaker afterwards explained in detail the various items of the balance-sheet and profit and loss account. He pointed out that the called-up capital amounted to £20,500, and stated that he differed from those who thought that the capital was too small. With a small capital it was easier to earn 10 per cent. without dashing into rash adventures. If, however, they found it necessary to make a call they would do so, but he believed that the shareholders would agree with him that it was better to go on with their small capital than to increase it. As to their investments, which stood at £46,500, they consisted principally of stocks and shares in undertakings which had been launched by the Company. They were stated at cost price, but a valuation had been made at what they considered a low figure, and finding that it was a question of no material difference they had resolved to keep the amount at cost price. They had sold securities for delivery on the 15th inst., amounting to £5,715, and they would continue to realise other investments as opportunity afforded ; but they had no wish to sacrifice their securities at what they considered under a proper value. The reserve fund might appear large, but they could not very well divide a higher rate of profit, for the reason that they proposed to divide all the cash they had.

Mr. J. B. BRAITHWAITE, Jun. (a Director), in answer to Mr. Pritchard, stated that all the securities held by them were believed to be first class, and they were all dividend-paying. No doubt Mr. Pritchard's suggestion would be considered by the Board, and if they saw their way to making an offer of some of the investments to the shareholders they might do so.

Mr. SYDNEY MORSE said he thought that the Board had taken a wise course in putting the amount stated to the reserve fund. He hoped that if any of the investments held by the Company were offered to the shareholders it would be at a price which would give them an advantage.

The resolution was carried unanimously.

The CHAIRMAN then proposed the following resolution :—

"That a dividend at the rate of 30 per cent. per annum for the half-year ending May 31, 1892, making, with the interim dividend of 20 per cent. per annum paid on November 30, 1891, 25 per cent. for the year, be and the same is hereby declared on the capital paid up on the ordinary shares."

Mr. B. H. VAN TROMP seconded the resolution, which was unanimously adopted.

On the motion of the CHAIRMAN, seconded by the Right Hon. Lord CLONCURRY, a dividend of £30 was declared on each of the founders' shares.

Resolutions were afterwards passed, making the dividends payable on the 15th inst., and re-electing the retiring Directors and auditors. A vote of thanks to the Chairman and Directors brought the meeting to a close.

The following is the Report of the Directors :—

The profit and loss account for the year ended May 31, 1892, shows a gross profit on the transactions of the year of £34,379. 4s. 5d. ; and, after deducting all standing charges, there remains a net balance available for distribution of £23,863. 12s. 11d. An interim dividend has already been paid on the ordinary shares for the first six months of the year at the rate of 20 per cent. per annum, and the Directors now recommend the payment of a further dividend upon the ordinary shares at the rate of 30 per cent. per annum for the past six months, and a dividend on the founders' shares of £30 per share. This will leave a balance of £20,863. 12s. 11d., which the Directors recommend should be applied as follows :—£20,000 to reserve ; £726. 0s. 1d. for writing off the preliminary expenses ; £137. 12s. 10d. balance to be carried forward in equal moieties on account of the ordinary shareholders and founders.

The amended Articles of Association recommended by the Directors have been adopted at two extraordinary general meetings of shareholders, and approved by the holders of the founders' shares, and have been registered as the Articles of Association of the Company.

The Directors have appointed as Managing Director Mr. Emile Garcke, M.Inst.E.E., formerly Managing Director of the Brush Electrical Engineering Company.

The Directors who retire this year are Mr. George Herring and Mr. B. H. Van Tromp, who, being duly eligible, offer themselves for re-election. The auditors, Messrs. Rait and Kearton, also retire, and offer themselves for re-election.

It is proposed to make the dividends payable on June 15th.

Consolidated Telephone Construction and Maintenance Company (Limited).

The eleventh annual ordinary general meeting of the Consolidated Telephone Construction and Maintenance Company (Limited) was held at the Terminus Hotel, Cannon-street, yesterday, under the presidency of Mr. C. L. W. Fitzgerald.

The SECRETARY (Mr. Charles Curtoys) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said : Gentlemen, I will now make a few remarks before moving the resolution declaring the dividend and adopting our report. You will observe from the report that the net profit for the year is £7,188. 4s. 8d., to which must be added the amount carried forward from last year, making a total sum of £8,904. 9s. 6d. An interim dividend has been paid on the preference shares of 3 per cent., and one of 2½ per cent. on the ordinary shares, and it is now proposed to pay a further 3 per cent. on the preference shares and 1 per cent. on the ordinary shares, which will make 6 per cent. for the year on the preference, and 3½ per cent. on the ordinary shares. It is with extreme regret that we on this side of the table are obliged to present you with accounts which are not so favourable as on past occasions ; and no doubt you are anxious to know how this state of affairs has been brought about. I will endeavour to explain shortly what has happened, but first I should like to call your attention to the debit side of the accounts. There are several items which will not appear again next year; for instance—Colonel Gouraud £550, Crystal Palace Exhibition £174. 17s. 9d. ; and further, we have had considerable extra expenditure in advertising, stationery, &c., also the establishment of agencies. All these items amount to a considerable sum, which will be saved next year. Your Board, finding the figures unfavourable, decided unanimously to relinquish half their fees for the year ending March 31, 1892, and no doubt the shareholders will be gratified to know this. Gentlemen, you see on the credit side of the account the sum of £6,665. 15s. as profit on manufacturing. Last year it was £9,619. 1s. 3d., and has averaged some £8,000 to £9,000 each year since the year 1885. You will ask why has the profit fallen some £3,000. I will tell you. You will recollect that last year the patents held by the National Telephone Company expired, and consequently the United Kingdom became free ground for anyone to compete for the telephone business. The foreigners, German, French, and Americans especially, were not slow to take advantage of this fresh market, and they one and all started agencies in London and elsewhere, and in addition hosts of small English firms started making telephones. You are aware that we, your Directors, have always endeavoured to manufacture a first-class highly-finished article, at a not very extravagant selling price, but still at a substantial one. Now, what we found was that the foreigners and others began to offer telephones at cheaper prices than we were selling at, and so there was no alternative but for us to reduce our prices also ; and this state of affairs has gone on for the last six months. Unfortunately, our competitors offer telephones for about 20s. to 30s., and of course our customers ask us to supply at about that price also. The result is that we do not sell so many of our high-class expensive instruments, but get orders for a lower-class instrument, which yields a lower profit. Again, many foreign nations have lately put very heavy duties on goods sent out to their countries, and this of course has a detrimental effect on our business. This, gentlemen, is how we account for the falling off in our profits.

The measures we propose to adopt to meet this competition are as much as possible to reduce our fixed charges, if I may call them so, and to manufacture with the greatest economy ; and I may tell you we have splendid labour-saving machinery in our factory, nearly all of which has been acquired by your present Board. We have further established agencies throughout the United Kingdom, and we are now organizing a telephone rental business for private lines, such as from house to stables, and shop to factory, and so on. We hope that this business may prove of a lasting nature, and I believe it will be so, in spite of the enormous competition which is going on for this class of business. One thing I will say, it will not be for want of trying that we shall not succeed. Your factory is in perfect order ; we can manufacture cheaply, and are ready to turn out thousands of telephones. All we want is the public to come for them. I should tell you that the demand by the public has not been nearly so great as I anticipated it would be on the expiry of the patents; but it may come for all that. As to the subsidiary companies, Austria has done well with 325 new subscribers, while Portugal only shows an increase of 65; the financial crisis in Portugal has had a detrimental effect on the business of the Anglo-Portuguese Telephone Company, and the Directors of that Company considered it would be unwise to pay a dividend. The consequence to us is that the Edison-Gower-Bell Company was unable to pay us the interest on our preference shares. In Austria the Government intimated that they intended to buy up our subsidiary Company, the Telephone Company of Austria, a business which we had created during the last ten years. Two colleagues and myself went to Vienna in March and also in October, last year. An agreement has been signed by the Austrian Government, and by it they are to take over the business from January 1, 1893, paying us the purchase-money during the first fortnight in January. When we have received this money we shall take the shareholders into our confidence as to what is to be done with it; events at present point to a return of capital, and it may possibly be a remodelling of our balance-sheet. The law-suit by the Edison-Gower-Bell Company against infringers of our patent in Belgium still goes on, and we are told that some very important decision is now near at hand. I may tell you that it is a decision on a technical point, which point was fought out in Paris the other day, and given in favour of our contention. That the Belgian Courts will hold the same view is to be hoped for your sakes. In conclusion I wish to assure you that your Directors are doing everything in their power to put a more favourable aspect on your business ; and as your interests and ours are identical, you may feel confident that we shall do the best we can for you. The Chairman concluded by moving the adoption of the report and accounts and the declarations of the dividends recommended.

Sir ALEXANDER ARMSTRONG seconded the motion.

Mr. PERRING asked why the Directors offered preference shares to the shareholders, knowing that they were to receive a large sum of money from the Austrian Government next year.

The CHAIRMAN replied that they did so simply because they wanted the money, and because they could not be quite certain that they would get it from the Austrian Government to suit their convenience.

The motion was then agreed to.

Digitized by Google

On the motion of the CHAIRMAN, seconded by Mr. H. GRÈWING, the retiring Directors, Messrs. J. H. Buckingham and R. Van Zeller, were re-elected; as were also the auditors, Messrs. J. G. Griffiths and A. E. Green, on the motion of the Chairman, seconded by a shareholder.

A vote of thanks having been accorded to the Chairman the proceedings terminated.

Western Counties and South Wales Telephone Company (Limited).

The seventh annual general meeting of the Western, Counties and South Wales Telephone Company was held on Wednesday at the Grand Hotel, Bristol, under the presidency of Mr. Charles Nash, Chairman of Directors.

The report of the Directors, which will be found below, was taken as read. In moving its adoption,

The CHAIRMAN said he could not help expressing regret that that was probably the last annual meeting of their Company in its separate character, or rather as an independent undertaking. After quoting the paragraph in the report which pointed to the reasons which led to that alteration, he said: Of course the consideration of the terms upon which the amalgamation could be carried out was a difficult matter, and he would say a few words upon it, although it would be premature to go into it, as it would be necessary, as they knew, to hold a special meeting. They had endeavoured to put the favourable features of their concern before the National Company in the strongest light, and they were aided in this by their able general manager, Mr. Lewis, and his assistant, Mr. Prout, and others; and although they did not get such terms as they had hoped or such terms as they thought the value of the Company entitled them to, they were, however, able to modify the views of the National Company, and at length got a better price than they at first contemplated. Under these circumstances he thought it desirable that the proposed terms should be accepted; and although it might be a little irregular, as that was not the meeting for submitting the amalgamation resolution, it was certainly desirable that he should now mention the terms. The National Company were prepared to give a fair percentage on the market value of the Western Counties Company's shares, and when they considered that their ordinary shares had only earned two dividends besides the one which would be proposed at that meeting, he thought the shareholders would see that they would not be at all injured by accepting the proposed terms. Those terms were:—One £5 ordinary share in the National Company, with the dividend to April 30, for 18 ordinary shares in the Western Counties Company. The dividend on the National shares had been at the rate of 6 per cent, and that was equal to 1⅞ per cent. on the par value of the ordinary shares, and to 6¾ per cent. on 5s., which was the average recent quotation for their shares.

Mr. GEORGE WHITE said that he did not see the necessity for the proposed amalgamation, as the Company was now going on very well, and seemed to have taken a fresh lease of life. He then, with the Chairman's permission, read a document sent by the members of the Bristol Stock Exchange to the Board of Directors, which was as follows:—"Stock Exchange, Bristol, June, 1892.—To the Directors of the Western Counties and South Wales Telephone Company (Limited).—Gentlemen: We, the undersigned members of the Bristol Stock Exchange, who are either shareholders in the Company or interested on behalf of clients, have perused the recent circular to the debenture holders and shareholders. We desire to protest against the whole tone of the circular, especially that portion in which the shareholders are practically threatened by their own Directors with a winding up of the Company unless they submit to inequitable terms. We must point out that in stating the 'only courses open,' the Directors should have mentioned that, by calling the necessary meetings of shareholders, authority should be obtained for a further issue of capital, and, as we know, it has been suggested that the National Company might endeavour to block such an issue, we would point out the fact of the National Company's power, arising from their holding of bonus shares for which they paid nothing, makes it unlikely they would attempt to use their power in any such manner. In addition to which we would remind you that the Government have expressed their intention to assist the development of telephone enterprise, and we therefore believe that were the National Company to attempt to inflict such a wrong on this Company, the Government have ample power to bring the necessary influence to bear with reference to the National Company's licences as would effectually prevent such an injustice to the shareholders of a Company which has done so much to develop the telephone in this district. Moreover, we desire to express our opinion that a respectable company of such standing as the National Company would never think of attempting such a coercion. Referring to the report and accounts, which have been just published, we consider that there is no reason why you should sell the undertaking, except upon proper terms; and, seeing that the present revenue of the Company exceeds the income which would accrue to the shareholders under the proposed sale, and that no return is being secured to the Company for its splendid future, we are of opinion that you will best consult the interests of the shareholders by refusing to sell the undertaking upon the present inadequate terms." He felt that such a letter had never before been addressed to a Board of Directors and sent so unanimously as it was by the members of the Bristol Stock Exchange; and he trusted the Board would reconsider the matter, and lay before the shareholders the whole of the alternatives, which would enable them to properly consider the subject.

Much discussion followed respecting the document; and ultimately, Mr. MARK WHITWILL having seconded the motion for the adoption of the report, it was put to the meeting, and adopted.

Upon the proposition of the CHAIRMAN, seconded by Mr. R. CORY, a dividend at the rate of 6 per cent. upon the preference capital for the year ended December 31, 1891, was declared.

A dividend of 1 per cent. upon the ordinary shares was agreed to, upon the motion of the CHAIRMAN, seconded by Mr. FEDDEN.

The retiring Directors, Messrs. M. Whitwill and T. Pole, were re-elected.

Colonel JACKSON, of the National Company, in proposing a vote of thanks to the Chairman, desired it to be known that the local company could not issue fresh capital without the sanction of the National Company. There was an express agreement to that effect, and it was absolutely necessary that the Western Counties Company should appeal to the National Company. He could tell them the Directors of the Western Company had fought for the best possible terms.

The resolution was adopted, and the meeting terminated.

The following is the report of the Directors:—

Capital Expenditure.—The capital expenditure for the year ended December 31, 1891, was £20,956. 14s. 3d., making a total of £185,366. 6s. 5d. to date.

Revenue.—The gross revenue of the Company for the year 1891 was £52,224. 1s. 6d., against £46,860. 15s. for the year ended December 31, 1890. The amount of income carried forward to next year's revenue, as representing sums received in advance for periods extending beyond December 31, 1891, is £15,548. 7s. 11d., against £14,212. 19s. 1d. brought in from the previous year.

Maintenance.—The whole of the Company's plant has been fully maintained, and, where required, renewed out of revenue. The Company have continued to substitute, at considerable expense, a large amount of copper and bronze wire for iron, which has increased the efficiency and durability of the plant.

Working Expenses.—The working expenses, including maintenance and all working charges for the year 1891, have been £16,685. 10s. 10d. against £13,775. 18s. 1d. for the year ended December 31, 1890.

Dividend.—

Balance of net revenue account	£11,236	17	4
Dividend of 6 per cent. on the paid-up Preference share capital for the year ended Dec. 31, 1891	6,000	0	0
Balance for appropriation, as per statement at end of accounts	£5,236	17	4

The Directors recommend that a dividend at the rate of 1 per cent. be paid for the year on the ordinary shares, absorbing £2.811. 19s. 5d., leaving a balance of £2,424. 17s. 11d., from which will have to be deducted the amount which may be voted for the Directors' fees for the year 1891.

Growth of Business.—The number of subscribers to the exchange system and of private line renters has further increased, and the progress made during the year is considered to be satisfactory. The respective totals at the close of the years 1890 and 1891 were:—

	Exchange.	Private.	Total.
For December 31, 1891	3,268	803	4.071
For December 31, 1890	2,875	712	3.587
Increase in 1891	393	91	484

Mileage of Trunk and Renters' Wires—

Erected up to December 31, 1891	5,753 miles
Erected up to December 31, 1890	5.018 „
Increase representing new business during 1891	735 „

In addition to the above, 191 miles of wire have been renewed during the year.

Trunk Lines.—The Company has increased its trunk system, so that on December 31, 1891, it had 505 miles of trunk pole lines connecting towns with each other, carrying 2,383 miles of wire; against 470 miles of pole lines, carrying 2,182 miles of wire, at the corresponding date in the previous year.

Proposed Sale to the National Telephone Company (Limited).—It is within the knowledge of many shareholders that for some time past a gradual process of amalgamating the Provincial Telephone Companies with the National Telephone Company (Limited) has been in operation. It has been felt by your Directors that either an amalgamation must be effected between this Company and the National Company, or additional capital must be raised to meet the requirements of its important district, comprising the Western Counties and South Wales, for which the approval of the National Company would be necessary. After much discussion the former alternative has been adopted, and terms have been provisionally arranged for the consideration of the shareholders. A provisional agreement is now in course of preparation, which will be submitted to a special meeting of this Company with as little delay as possible. As soon as the provisional agreement has been finally settled full information of the terms of the proposed sale will be afforded to every shareholder by circular or otherwise.

The Post Office.—The Directors have pleasure in acknowledging the continued uniform courtesy of the permanent officials of the Post Office Department.

Retiring Directors and Auditors.—Mr. Mark Whitwill and Mr. Thomas Pole retire, the former by rotation and the latter by ballot, but are eligible for re-election. Messrs. Hudson Smith, Briggs, and Co. retire, but are eligible for re-election.

Taunton Electric Lighting Company (Limited).

An extraordinary general meeting of this Company was held on Thursday last week, to consider an offer made by a committee appointed by the Town Council to purchase the Company's works and undertaking at the price of £9,300.

Digitized by Google

Mr. J. H. BALE presided, and, after stating that the meeting was a statutory one, proposed—

"*That the offer of the Taunton Town Council to purchase the Company's works and operations, subject to the approval of the Local Government Board and Board of Trade, at the price of £9,300, be accepted.*"

Mr. WALDEGRAVE having seconded the proposition,

Mr. POTTER pointed out that the offer to purchase the works for £9,300 did not come from the Town Council, but the proposal emanated from the committees representing the Council and the Company, who had discussed the matter and agreed to that sum.

The resolution was carried unanimously, and the CHAIRMAN then proposed—

"*That the Directors be authorised to carry out the said sale in such manner and under such arrangements and conditions as they may think advisable.*"

Mr. KITE seconded; and the resolution having been also carried *nem. con.*, the meeting adjourned.

Elmore's German and Austro-Hungarian Metal Company (Limited).

The first annual ordinary general meeting of the shareholders in this Company took place yesterday at the Cannon-street Hotel; Mr. James Beck, J.P., in the chair.

The SECRETARY (Mr. J. Shurmer) read the advertisement convening the meeting.

The CHAIRMAN, in moving the adoption of the report and accounts, stated that the Directors had been very anxious to meet the shareholders, but it had been impossible to make up the accounts without proper vouchers. As these vouchers were in the hands of an official auditor in Germany in connection with the establishment of the German Company, the accounts could not be made up earlier. They had not, however, been idle while the delay had been going on. Owing to the slow process of the German Company law they did not get their actual registration nor their legal position in Germany until quite the last days of April. They stood now before the shareholders with this business completed. When they formed the German Company they paid them about £12,500, and a large proportion of this sum was in the hands of the former at the time the accounts were made up. The report was, he thought, a plain and unvarnished statement of all that the Directors had been doing, and it brought their affairs up to a very recent date. They considered that Germany was a better field for them to begin operations in than Austria, and they had not thought it advisable to do more than they had done; they thought it would be wise to make their footing good in one country before they moved to any extent in another. At their last meeting he told them that they were negotiating for a factory at a place called Schladern, and this property had since been acquired and completed, and they were at that moment actually at work at it. It was an important structure, standing on a river called the Sieg, and it had an important water privilege—that of a fall of about 16ft. close to their works. The estate had, besides the water power, two capital stone quarries and a brick field. They had filled up the lower story of the main building with tanks and machinery for depositing copper in the form of tubes. They had 40 tanks there, but they were not all at work, as there was some difficulty about the mandrils. They had only been at work four or five weeks since they obtained permission, and part of their working had been for their own purposes—that was, making mandrils from the original ones which they had obtained from other sources. The position of the factory was a very good one, with railway communication within about 800 yards, a road to the station, and an iron bridge across the river for the purpose of their works; the bridge being made and maintained by the railway company at no expense to this Company. They began with 25 orders, and they would find plenty to come in to keep them going. As to profits, an average price of 1s. per pound, which they believed they would realise, would give them about £30 a ton profit, and when they worked up to 20 tons a week, or 1,000 tons a year, that would give them £30,000. They would, however, have to extend their works to reach this point; the works now could only turn out five tons a week. They were not proposing to increase the capital; and the projected conversion of the debentures into preference shares would be an advantageous arrangement for the Company.

Mr. JOHN MACFARLAN seconded the motion, which was carried, after the CHAIRMAN had replied to certain questions chiefly on the accounts.

On the motion of the CHAIRMAN, seconded by Mr. GLADSTONE (a shareholder), the following resolution was carried:—

"*That the capital of the Company be increased to £250,000 by the creation of 25,000 new shares of £2 each.*"

The CHAIRMAN next proposed, and Mr. MACFARLAN seconded the following resolution, which was agreed to:—

"*That such new shares, and the 25,000 shares now unissued of the original capital of the Company, shall be called 'Preference Shares,' and shall be entitled, out of the profits available for distribution in each year, to a preferential dividend of 7 per cent., and also to participate pari passu with the holders of the existing issued shares of the Company in the surplus profits of each year, after a dividend of 10 per cent. has been paid for such year on such existing issued shares of the Company, which shall in future be called 'Ordinary Shares.'*"

The retiring Directors and auditors were reappointed, and the usual vote of thanks closed the meeting.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

LONDON ELECTRIC WIRE COMPANY (LIMITED).—This Company was registered on May 31st with a capital of £50,000, in £5 shares. The objects are: To acquire and take over as a going concern the business of manufacturers of electrical wire and other apparatus, carried on by Thomas Willey and John Willey, under the style or firm of "The London Electric Wire Company," at Playhouse-yard, Golden-lane, in the City of London, and to carry on in the United Kingdom and elsewhere the business to be acquired, and all or any of the following businesses, viz., the manufacture of insulated wires, cables and appliances for telegraphs, telephones, and any other electrical purpose, the fitting up of electric installations for lighting or other purposes, the manufacture of electric motors or other machinery, and the buying and selling of any goods or apparatus in any way connected with the foregoing. The first Directors are Thomas Willey and John Willey, each of whom may hold office for life or until resignation.

ELECTRICITY SUPPLY COMPANY FOR SPAIN (LIMITED).—The annual return of this Company, made up to January 7, 1892, was filed on April 30th. All the shares have been taken up, of which the 100 founders' shares have been issued as fully paid. Upon the remaining 19,900 ordinary shares the full amount has been called, and all calls (£99,500) paid.

ELMORE'S AMERICAN AND CANADIAN PATENT COPPER DEPOSITING COMPANY (LIMITED).—The statutory return of this Company, made up to May 17th, was filed on the 31st. 44,788 priority and 35,000 deferred shares have been taken up, of which the deferred shares have been issued as fully paid. Upon the 44,788 priority shares the full amount has been called, resulting in the payment of £80,319, and leaving £9,257 in arrears.

INDO-EUROPEAN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 11th, was filed on the 19th. The Company was registered on April 6, 1878, with a capital of £450,000, divided into 18,000 shares of £25 each. At the time of making up, 17,000 shares had been taken up, the full amount called upon each, and all calls (£425,000) paid.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to May 20th, was filed on June 2nd. The Company was registered on November 26, 1887, with a capital of £250,000, in £10 shares. At the time of making up, all the shares had been taken up, and 2,132 shares had been issued as fully paid. Upon the remaining 47,868 shares the full amount had been called, resulting in the payment of £478,271. 9s., and leaving £408. 11s. in arrears.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 26th, was filed on June 2nd. The Company was registered on April 29, 1873, with a capital of £1,350,000, divided into 67,500 shares of £20 each. The capital has been changed to £1,500,000, divided into 65,871 shares of £15 each, and 66,258 shares of £7. 10s. each. Of these shares, 64,242 shares of £15 each, and 66,258 shares of £7. 10s. each, have been taken up, the full amount called, and all calls (£1,460,565) paid, while £565 has been paid on 75 shares forfeited.

CITY NOTES, &c.

BELL TELEPHONE COMPANY OF AMERICA.—This Company has declared the regular quarterly dividend of 3 per cent., and an extra 3 per cent. in place of the extra 6 per cent. of last year, labour troubles reducing the profits.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended June 5th were £782, as against £775 for the corresponding period of last year, being an increase of £7. The total receipts to date, from January 1st last, amount to £18,191, against £16,919 in the corresponding period of 1891, being an increase of £1,272.

COMMERCIAL CABLE COMPANY.—Notice is given that a quarterly dividend of 1¾ per cent. upon the outstanding stock of this Company will be paid on July 1st next, from its net earnings, to all shareholders of record on June 20th. The transfer books will be closed on June 20th and reopened on the morning of July 2nd.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the month of May amounted to £2,132, as compared with £2,163 in the corresponding period of last year, a decrease of £31.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for May, 1892, amounted to £22,000; and from January 1st to May 31st to £104,800. In the corresponding months of 1891 and 1890 the amounts were £114,000 and £105,800 respectively.

MALTA AND MEDITERRANEAN GAS COMPANY (LIMITED).—At the adjourned general meeting of this Company, on Tuesday last, Mr. John B. Paddon, the Chairman, said that in October last some proposals were made to the Governor of Malta by Mr. Preece for the supply of electric light to the military and naval establishments and for the public lamps. The Government were, however, unable to see any advantage to be gained in the adoption of those proposals, and their consideration had been adjourned.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the fortnight ended May 31, 1892, amounted to £3,229, as compared with £2,837 in the corresponding period of last year, a decrease of £392.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended June 3, 1892, after deducting

Digitized by Google

17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,032.

WESTERN UNION TELEGRAPH COMPANY.—The earnings for the quarter just ended show a net increase of $250,000. The net surplus for the year shows an increase of $750,000. The regular dividend of 1¼ per cent. has been declared.

CRICKET AT MALTA.—A match was played at the Marsa, Malta, on the 26th ult. between the Eastern Exiles and the C. S. "Amber" elevens, resulting in an easy victory for the Exiles by an innings and 83 runs. Score :—

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 735.—Vol. XXIX. FRIDAY, JUNE 17, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The electrical attractions at the Royal Society on Wednesday were much the same as those of the May conversazione. Prof. Vernon Boys again showed his photographs of flying bullets, and announced that he had succeeded in reducing the duration of the photographying spark from $\frac{1}{3000000}$th of a second to $\frac{1}{11000000}$th, and that he hoped to bring it down to $\frac{1}{20000000}$th. This result has been attained by merely shortening the Leyden jar circuit and substituting copper strip for copper wire, thus diminishing the inductance.

Francis Hauksbee's "Physico-Mechanical Experiments" is an interesting old book, "printed by R. Brugis for the Author, and Sold only at his House in Wine Office-court, in Fleet-street, 1709," and contains "An Account of several Surprising *Phenomena* touching *Light* and *Electricity*, Producible on the *Attrition* of Bodies, with many other Remarkable Appearances not before observ'd." Hauksbee was a Fellow, Curator of Experiments, and Assistant Secretary to the Royal Society; he greatly improved the experimental air-pump, which was then a very handsome piece of carved furniture, and he appears to have been the first to use glass in frictional electric machines.

Hauksbee made a number of experiments on the elasticity of air. More than once he seems to have thought that he had succeeded in giving a permanent set to the "spring of air." In one of these researches, intituled "An Experiment about disturbing the Spring of Air," he arrives at the conclusion "That the Springs of Air may be so disturbed by violent Impulses or Strong Compressions as to require considerable time to recover their Natural Tone and Temper and Compleat Restitution." On another occasion he compressed air in a flask to about five or six atmospheres, and "this Air continued in that state of violent condensation" for more than four months, when it was found that, in consequence of the "intemperate heat of the weather," the cement failed "to resist the Efforts of the mighty Spring of the inclos'd Air." Something went wrong with the mercury gauge, which remained at $\frac{1}{4}$ inch after the vessel was opened; but he concludes that "the injur'd Springs could not recover themselves," and "that their long detention in that violent state must needs have made them unable to unwind themselves so far as was necessary to their own Discharge." Hauksbee then asks "What kind of Liquid would so many Atmospheres of condens'd unelastic Air compose? Would not Terrestrial Animals be suffocated in it, as they would be in Water or other Fluids?" and after two other questions, "Is it impossible that Air by this means should become a Visible, Palpable Fluid; and be Subject to some of the same managements that other Fluids are?" It has been reserved for Prof. Dewar, 183 years later, to hand to Lord Kelvin at the Royal Institution on Friday last a wineglass of this very Visible, Palpable Fluid.

The short space of seventy minutes gave barely time for Prof. Dewar's experiments, and, as in Mr. Tesla's lecture, there were many points about which explanations were greatly needed. It seemed indeed as though Hauksbee's idea had been carried out to the letter, and in the liquid, at first boiling violently, but soon coming to gentle effervescence and finally clearing, the air appeared truly to have suffered a permanent set. Many tons on the square inch at ordinary temperatures would not have retained the air in a liquid form; and yet there it lay in an open glass. The explanation is that a liquid cannot turn into gas without absorbing heat. While first bubbling briskly, it was absorbing the heat of the vessel into which it had been poured, and when this had been thoroughly chilled there was nothing but the surrounding air from which to draw further supplies of heat; and this surrounding air consisted, of course, of the just liberated gas at the boiling temperature of nearly $-200°C$. The radiation from the audience was no doubt the main source of heat, and this was too feeble to keep the liquid boiling, so it had perforce to evaporate moderately.

The "intemperate heat of the weather" and "hot state of the Ambient Medium," which brought Hauksbee's experiment to a close, interfered greatly with the preparations for the experiments on Friday evening. At the last moment supplies of ice had to be borrowed from the neighbouring clubs to assist in cooling the apparatus. The liquefaction of oxygen and of atmospheric air was brought about, we understand, not by a combination of pressure and cold, as in the researches of Pictet and Cailletet, but by reduction of temperature alone. The gathering up of the liquid oxygen upon the pole-pieces of Faraday's great magnet was a notable experiment that will long be remembered by all those who saw it.

The remarkable fact demonstrated at Prof. Dewar's lecture on liquid oxygen, that air is liquefied without change of composition, is deserving of a little closer attention than was

Digitized by Google

possible in the single hour allotted to a Friday evening discourse at the Royal Institution. Nitrogen, although boiling at a temperature 10° C. lower than oxygen, is liquefied together with it at the same temperature, because the liquefaction is effected in an atmosphere in which the pressure of the nitrogen exceeds that of the oxygen—viz., ordinary air. It was also stated, and proved by direct experiment, that the liquefied air became fractionated by spontaneous evaporation, the nitrogen vaporising and leaving the oxygen. But it is difficult to understand why that which held good for the process of liquefaction should not do so for that of gasification. Liquid air gasifying in free contact with the atmosphere would do so under a pressure of nitrogen about four times that of the oxygen, and the vaporisation of the former would be correspondingly retarded, just as its liquefaction was previously aided. According to this view, therefore, liquid air should evaporate under ordinary atmospheric pressure without undergoing fractionation. The matter certainly stands in need of elucidation; but, unfortunately, it is not given to most experimenters to deal with liquid oxygen and nitrogen by the litre.

Prof. Dewar mentioned in his peroration that the resistance of micro-organisms and seeds to intense cold went to support the suggestion of Lord Kelvin, that life might have entered this world on the back of a meteorite, the difficulty arising from the low temperature of space being thus overcome. A life-germ capable of such transmission would have, however, to endure extremes of temperature at both ends of the scale, as the temperature of a meteorite falling through an atmosphere of ordinary tenuity is raised to a point at which all life, as we know it, ceases. One would have to postulate a planet devoid of atmosphere to avoid the destructive distillation of a celestial visitant of this description.

Good old Francis Bacon would have thoroughly enjoyed Prof. Dewar's lecture. "It seemeth," he writes, in the "Sylva Sylvarum," on "Experiments Solitary touching the Version and Transmutation of Air into Water," "that there be these ways (inlikelihood) of *Version of Vapours* on *Air*, into *Water* and *Moisture*. The first is *Cold*, which doth manifestly Condense; as we see in the *Contracting of the Air* in the *Weather-glass*; whereby it is a degree nearer to *Water* . . . And the experiment of turning *Water* into *Ice* by Snow, Nitre, and Salt would be transferred to the turning of *Air* into *Water*. The second way is by *Compression*. . . . But this is like to do no great effect; except it be upon Vapors, and gross *Air*, that are very near in Degree to Water." Was Bacon in this "experiment," which appears between "Experiment Solitary touching the Venemous quality of Man's Flesh" and "Experiment Solitary touching the *Helps* towards the *Beauty* and *good Features of Persons*," nearer the mark, just a century earlier, with his wild speculations, than was Hauksbee with his leaky gauge? Are there any of us to-day so far ahead of our times? We may smile at Bacon and Hauksbee, but those men could think straight at times.

A most commendable feature in the construction of the galvanometers which were shown at the last meeting of the Physical Society was the mechanical arrangement of the moving parts in a tube, which can be easily detached from the heavier and more bulky part which constitutes the body of the instrument. We do not know whether this system first came into general use with the Evershed voltmeters and ammeters; but it has now become a most important feature, not only in economy of manufacture but in affording the utmost facility for adjustment and repair.

In the important Paper by Prof. Ayrton, Dr. Sumpner, and Mr. Mather on "Galvanometers," in 1890, the system of "scale divisions" in use at the Central Institution was explained. It was, we believe, as accidental as the adoption of the narrow gauge by Stephenson, and consisted of millimetre divisions at two metres distance, or half millimetres at a metre, these being the scales and distances which happen to have been in common use at the laboratories of that Institution. But it can hardly be expected that ignorant outsiders who have not had the privilege of passing through the classes in those laboratories can remember exactly what is meant by scale divisions; and we thoroughly agree with Prof. S. P. Thompson's suggestion that angular measure or tangents should be adopted; especially in attempts to compare different instruments by "figures of merit." One Central Institution scale division means an angular deflection, the sine or tangent of which is 0·0005, or 1 minute 43 seconds of arc. One degree would be equal to 34·9 of these divisions.

The magnetic and diamagnetic properties of miscellaneous non-metallic substances are well known by the experiments of Faraday, but the forces are as a rule so feeble that they are neither useful nor detrimental in practical work. At the Physical Society last week it was pointed out that with the powerful field and delicate construction of the modern d'Arsonval galvanometer, silk, paraffin, and copper exhibited sufficiently distinct magnetic properties to give rise to difficulties in the use of these instruments; ebonite also was found to be distinctly magnetic, or to have what was called a magnetic polish.

It has been thought that the diamagnetic property of copper has been observed in some dynamos as an apparent increase of the air gap, but the effect was probably due to armature reactions. We have searched through more than a dozen books for the value of the permeability of copper, and as a last resort looked at J. E. H. Gordon's "Physical Treatise on Electricity and Magnetism." Faraday's list including gum arabic, fresh beef, apple, and bread was given there *in extenso*, and the section closes with the following remarkable passage: "The strength of the pole of an electro-magnet having an iron core may be as much as from 32 to 45 times the magnetising force, while with a bismuth core it would only be about $-\frac{1}{4000}$ of it." In the absence of more accurately expressed information, a variety of false conclusions might be drawn from this. Maxwell put it, "the ratio of the magnetisation to the magnetic force which produces it is exceedingly small, being only about $-\frac{1}{4000}$ in the case of bismuth." To-day we should say that κ, the susceptibility of bismuth, is $-\frac{1}{4000}$, or that μ, the permeability, is, according to Ewing, 0·99882.

In a recent number of the *Transactions* of the Reale Accademia dei Lincei, Dr. Angelo Bauti describes experiments which he has made on the magnetisation of nickel under the influence of certain mechanical stresses, with special reference to the remarkable discovery first made by Nagaoka, that a nickel wire, when suspended in a steady magnetic field and subjected to longitudinal pull, has its magnetic polarity reversed when one end of it is twisted back and forth, the other end being held fixed. The end, which is a north pole when the twist is towards one side, becomes a south pole when the twist is to the other side; and this reversal of polarity occurs in every twisting, although the magnetic field continues to act in one direction.

Dr. Bauti's observations confirm the earlier ones of Nagaoka, and show that the reversal of effect shown by the magnetometer is due to a genuine reversal of magnetisation, which affects the whole mass of the wire. With a sufficient amount of torsion he finds that the phenomenon of reversal of polarity occurs even when there is no longitudinal pull—a conclusion which forms the chief novelty in his results. From this, taken in conjunction with Ewing's experiments on the effects of simple pull in nickel (which showed no reversal of polarity when the wire was alternately loaded and unloaded), Dr. Bauti concludes that torsion is the necessary and sufficient condition to produce the phenomenon of inversion of polarity; longitudinal pull, while it accelerates the action, being neither necessary nor sufficient in itself to produce it.

Following the now common custom of the electrical press, *L'Industrie Electrique* devotes its issue of June 10th to central-station matters. Amongst other things it publishes a lengthy list of French provincial and colonial electric lighting stations, together with a map showing their location. According to this list there are over 250 stations actually in existence or about to come into existence; but as more than three quarters of them are of less than 100 horse-power and many are of only 10 or 20 horse-power, this formidable total is scarcely a trustworthy criterion of electrical progress in France. Perhaps the most noticeable features of central-station enterprise across the channel are the great utilisation of water-power, the prevalence of overhead wires, and the marked preference for continuous currents. In some 40 per cent. of the instances where particulars as to the source of power are given, water-power alone is used, and out of 242 cases distribution is effected by alternate currents in 204, and by overhead wires in 224; evidently there is no French equivalent to the Board of Trade.

The Imperial Institute having arrived at a sufficiently advanced stage to invite inspection, and to provide accommodation for a preliminary luncheon on Saturday next, a pamphlet has been published containing a full description of the building, and an attempt to explain its mission. The Colonial Office and the Royal Colonial Institute will no doubt continue to exercise their functions; but as nobody seems to have a clear idea of what is going to be done at the Imperial Institute, we venture to suggest that the magnificent hall and corridors could be used with great advantage for the conversazioni of scientific and other societies.

Prof. Helmholtz.—The Académie des Sciences has elected Prof. Helmholtz a foreign associate, in the place of the late Emperor of Brazil.

Denby v. Scott and Mountain (Limited).—In the Outer House of Session on Wednesday, judgment was given in this appeal for the defendants.

The Azores Cable.—The contract concluded between the Portuguese Government and a French company for laying a cable to the Azores was signed on Saturday last.

Bremen.—The Bremen Street Railway Company's electrical line was officially opened on the 28th ult. This line is the first in Germany operated on the overhead trolley system.

Personal.—Mr. J. Harrhy, local manager of the Eastern and South African Telegraph Company at Port Nolloth, is leaving the coast, owing to that station being disconnected by cable.

Electrical Communications with Lightships.—The Government are about to carry out experiments on the connection of the lightships on the Goodwin Sands by telegraph with the shore at Deal.

Blackburn.—In view of the Blackburn Electric Lighting Order the local tramway company have applied to the Corporation to know whether they would be prepared to supply them with electricity.

Animal Electricity.—The Aldini Medal for Animal Electricity has been awarded to Dr. A. Waller, Lecturer on Physiology, St. Mary's Hospital Medical School, by the Bologna Academy of Sciences.

Electrical Bills in Parliament.—On Monday last the Liverpool Overhead Railway Bill, the Baker-street and Waterloo Railway Bill, and the Great Northern and City Railway Bill were read a third time.

Cable Restorations and Repairs:—

	Date of Restoration.
Repairs.—Mossamedes-Benguella	June 13th.
	Date of Interruption.
Interruptions.—Bissao-Bolama.....	April 23rd.

The American Philosophical Society.—At a meeting of the American Philosophical Society, Philadelphia, on May 20th, it was decided that the 150th anniversary of the foundation of the society should be celebrated in 1893, and a committee was appointed to make the necessary arrangements.

Royal Institution.—At the general monthly meeting of this Institution on Monday last, the special thanks of the members were returned for the following donations:—Mr. Bloomfield Moore, £80; Sir David Salomons, Bart., £50; Mr. Charles Hawksley, £50; for carrying on investigations on liquid oxygen.

The Western and Brazilian Telegraph Company.—This Company has received telegraphic advices of the successful laying of the duplicate cable between Rio Janeiro and the River Plate, thus completing the direct duplicated system of their telegraphs between this country, Brazil, Uruguay, and the Argentine Republic.

Obituary.—Mr. James Radcliffe, telegraph superintendent to the Great Northern Railway Company, died at Retford on the 2nd inst., after a few days' illness. Mr. Radcliffe was born in 1828, and entered the service of the Electric Telegraph Company in 1848 at Manchester. In 1870 he became telegraph superintendent to the Great Northern Railway Company, remaining in that capacity until his death.

Lightning.—On Friday last Mr. H. C. L. Lovett, an undergraduate of Christ's College, Cambridge, was struck dead by lightning. On Sunday no fewer than three cases of churches being struck by lightning occurred in Spain. At Melias, in the province of Orense, the parish church was struck, and 10 persons were killed on the spot, while 28 were injured. At about the same time another church, at Mucientes, in Valladolid, experienced a similar visitation, five people being killed and several injured. The famous cathedral at Burgos was likewise struck by lightning. This cathedral is unprovided with a lightning conductor.

Royal Society.—Amongst the Papers down for reading yesterday before the Royal Society were the following:—Lord Armstrong, F.R.S., "On a Multiple Induction Coil Machine and its Results;" the late Prof. J. Thomson, F.R.S., "On the Beams of Light seen with Partially Closed Eyelids;" J. Brown, "Voltaic Cells with Fused Electrolytes;" J. B. Peace, "On the Potential Difference required to produce a Spark between two Parallel Plates in Air at Different Pressures;" F. Lydall and A. W. S. Pocklington, "Magnetic Properties of Pure Iron;" and T. Andrews, F.R.S., "Electro-chemical Effects on Magnetising Iron—Part IV."

The Atomic Weight of Oxygen.—Mr. R. Lehfeldt writes as follows to *Nature*:—"I notice that Lord Rayleigh gives the following summary of results on the atomic weight of oxygen:—Dumas, 1842, 15·96; Regnault, 1845, 15·96; Rayleigh, 1889, 15·89; Rayleigh, 1892, 15·882, showing the remarkable fact that the atomic weight has been steadily decreasing for the last 50 years. I would suggest, as the explanation of this, that the increased population of the world, together with the great consumption of coal, have caused great wear and tear of these atoms, so that they are now mostly deficient in weight. It would seem, in fact, desirable that a Congress of chemists should be called to consider the question of providing for the renovation of the oxygen supply, and issuing trustworthy atoms of the standard weight, 16, as sealed patterns."

The Electric Discharge.—At a recent meeting of the Cambridge Philosophical Society, Prof. J. J. Thomson read a Paper on the pressure at which the electric strength of a gas is a minimum. Prof. Thomson showed that when no electrodes were present the discharge passed through air at a pressure somewhat less than that due to 1/250mm. of mercury; the discharge passed with greater ease than it did at either a higher or a lower pressure. Mr. Peace had lately shown that when electrodes were used the critical pressure might be as high as that due to 250mm. of mercury, so that as the spark length was altered the critical pressure might range from 250mm. to 1/250 of a mm. This involved the possession by a gas conveying the discharge of a structure much coarser than any recognised by the kinetic theory of gases. Prof. Thomson suggested a theory of such a structure, and showed that the theory would account for the influence of spark-length and pressure on the potential difference required to produce discharge.

Copper.—A correspondent of the *Economist* points out in the issue of that journal of June 11th that the arrangement with regard to the restriction of the output of copper, referred to in our last issue, only binds the American and European producers, and that there is nothing to prevent other countries increasing their shipments. Already the shipments from Chili, in consequence of the close of the revolution, are considerably in excess of those of last year, and promise to increase still further. With regard to the consumption of copper, it is pointed out that from the figures of Messrs. H. R. Merton and Co. the deliveries in England and France during the 12 months (June 1, 1891, to May 31, 1892) were 112,035 tons as against 139,075 tons in the corresponding period of 1890, and 145,796 tons in 1889-90. This would seem to indicate that the lower prices which have recently obtained have been consequent on reduced consumption. The correspondent of the *Economist* is of opinion that it is very probable that stocks have increased by several thousand tons during the past year.

Boiler Test.—Mr. Bryan Donkin, jun., and Prof. Kennedy in the course of their standardised steam-boiler experiments, tested a new portable locomotive type of boiler with a steel shell, by Messrs. Marshall and Co. It was working without any brickwork protection, and was not housed in any way. The boiler got up 70lb. of steam in 39½ minutes, starting all cold. The boiler was lagged in the usual way, and the steam, which was kept at about 61lb. during the test, was used to supply a compound steam-engine. The general dimensions of the boiler were as follows:—Fire-box inside, 3ft. 3in. by 2ft. 11in., and 3ft. 1in. high from the fire-bars; diameter of barrel, 3ft. 7in., and 7ft. 9in. long, with 50 tubes 2½in. in diameter. The total heating surface of the boiler was 316 square feet. In the course of the eight hours' trial, the furnace burnt 960lb. of coal; and the equivalent evaporation per pound of coal from and at 212°. Fahr. was 10·78lb. of water, corresponding to 11·25lb. per pound of pure and dry coal. According to the balance sheet of the boiler, 69·8 per cent. of the total heat went to heating and evaporating the water; 18 per cent. is accounted for in the furnace gases; and 5·7 per cent. was lost by radiation—leaving 5·2 per cent. unaccounted for.

Electric Railway Accidents.—On Friday afternoon last a Mr. Alfred Edward Stewart was crushed under a carriage on the City and South London Electric Railway. At the inquest it transpired that a guard came up and asked the deceased and a friend whether they would like to see the engine at work. They replied in the affirmative. The guard having opened the door, the deceased stepped on to the engine and disappeared down the opening between the engine and the carriage. The space between the engine and carriage was about 7in. The width of the carriage platform of the first carriage was 3ft. The train was in motion at the time, and was about 100 yards from the Elephant and Castle Station. A juryman remarked that he had often been invited by the guards on the City and South London Electric Railway to view the engine. The jury returned a verdict of "death by misadventure," and severely censured the guard.—A cablegram from New York states that an accident resulting in three deaths occurred on the Atlantic and Chattahoochie River Electric Railroad, owing to a derailment.—Another electric railroad accident is also reported from Wheeling, Western Virginia, owing to an electric car coming into collision with a crowded passenger train. The car was completely demolished, and three of the occupants killed.

Prize for Researches in Physics.—For the year 1894 a prize of 2,000fr. is offered by "Schnyder von Wartensee's Foundation," for the solution of the following problems:—"As the numbers which represent the atomic heats of the elements still show very considerable divergences, the researches conducted by Prof. H. F. Weber on boron, silex, and carbon, regarding the dependence of the specific heats upon the temperature, are to be extended to several other elements, prepared as pure as possible, and also to combinations or alloys of them. Further, the densities and the thermic coefficients of expansion of the substances investigated are to be ascertained as carefully as possible." The treatises handed in by competitors for the prizes may be in German, French, or English, and must be sent in by September 30, 1894, at the latest. The work to which the first prize is awarded is to be the property of the Foundation, and arrangements will be made with the author regarding its publication. Every treatise sent in must have a motto on the title-page, and be accompanied with a sealed envelope bearing the same motto outside and containing the author's name. The treatises are to be addressed "An das Praesidium des Conventes der Stadtbibliothek Zürich" (betreffend Preisaufgabe der Stiftung von Schnyder von Wartensee für das Jahr 1894)."

Magnetic Leakage in Dynamos.—A great deal of energy that might be better spent, says *Industries*, is wasted over the discussion of the waste field in dynamos. In spite of the spread of knowledge of magnetic circuits, there still seems to be a fallacy lurking in the subject. Many writers still seem to think that a certain number of ampere turns on the field must produce a corresponding total number of lines of induction, and that if a large proportion of these pass round the armature there will be fewer left available to go through. This is a complete misunderstanding of the question. The only effect of increasing the leakage is to produce more lines. They do not cost anything, and do not matter, except for one thing. They decrease the permeability of the field magnets, so they demand slightly more iron in the fields. The only bearing leakage has on dynamo design is in altering the permeability of the fields. A compound dynamo, for instance, should not have its field permeability too high at no load, or its pressure will be unstable; on the other hand, at full load the permeability should not be so reduced that too much excitation is needed to give the desired pressure. Various methods of constructing ironclad dynamos still appear from time to time. Another form of the same fallacy consists in winding the field excitation round the armature to ensure that all the lines shall go through the armature. This results in ruining the ventilation to gain nothing.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 144.*)

12. Removal of Fault.—Before the fault comes inboard we may as well look at what is going on in the testing-room. Ever since the ship began to pick up cable in the direction of the fault, incessant work has been going on in this part of the ship, involving great skill and judgment, and not unfrequently some amount of anxiety. The nature of the work depends upon the kind of fault to be removed, and whether communication can be kept up with the shore during picking up. If the fault is one of high resistance, as is most often the case in these days, communication can be kept up with the shore, and from time to time, as picking up goes on, the superintendent of the station on shore may be requested to test the line while the ship frees or earths the end on board. The results so obtained are communicated to the ship, and, when taken together with those obtained on board, form a valuable means of arriving at the true position of the fault. An earth overlap would be tried at intervals, and probably a Mance from both ends. Kingsford's modification of the Blavier would also be tried, and the rate of polarisation carefully watched. If, on the other hand, it were not possible to communicate with the shore, as in the case of a low-resistance fault or total break, the ship would rely chiefly on the Kennelly test, with various strengths of current. A brief reference to these tests was made in the introductory remarks to this series in issue of February 12th, page 379; but as it is proposed to enter fully into this subject in a later chapter, we need not at the present stage do more than name the methods most likely to be used.

The question is often asked, "How near can you ascertain the position of a fault in a cable?" Well, sometimes as near as to a tenth of a mile, and at other times not within 15 or 20 miles. Perhaps the most average limits, however, fall somewhere about within five miles. These limits depend largely upon the nature of the fault and whether there are more faults than one in a given cable. The easiest fault to localise is a fracture in which the broken end is insulated, caused by the percha or rubber stretching and closing over it. A total break with a good earth connection probably comes next. Then there are faults of varied sizes, making partial earth; those which are smallest, and therefore of highest resistance, being the most difficult to localise. The greater part of a cable-ship's work on repairs now-a-days is in removing the latter class of faults of high resistance; for while the number of cables has gone on increasing by the laying of duplicate and triplicate lines, their manufacture has been so far improved, and the protection against the teredo so effective by the introduction of brass-taped cores, that faults are of less frequent occurrence than in former years, and are consequently removed upon their first appearance. Some 12 or 15 years ago, before the introduction of these cables, and in the days when there was one ship operating over a given mileage where now there are two—it was a common thing for faults to be so numerous that the ship had only time to deal with those which either totally interrupted traffic or through which messages were transmitted with great difficulty. Especially in the Straits, Java, and China Seas, the happy hunting grounds of the teredo, cables used to be in a chronic state of weak insulation, with, perhaps, bad faults on three or four at one time. In those days many laborious hours were spent in deciphering Morse signals on the recorder slip, shattered by kicks from the fault, and only saved from dying down to a straight line by frequent applications of copper current. Such faults could be easily broken down to from 10 to 40 ohms with 50 cells, and it was deemed a high resistance fault that could not be got down to a hundred or two. All this is changed to-day, telegraphic communication from one end of the world to the other by submarine cables being more reliable and constantly maintained; and faults, dealt with on first causing a lowering of the insulation, are of enormously high resistance, varying from 5,000 to 100,000 ohms or more. The higher the resistance of the fault the longer the charge current lasts, and the longer the testing current must be kept on before a reading can be taken. Further, as the fault polarises rapidly, it is very difficult to get a satisfactory test.

But we must take a turn in the testing-room, and make ourselves acquainted with the apparatus used. The testing-room on board most modern ships is situated on the upper deck, and generally about amidships. In climes under

> "Those blazing suns that dart a downward ray,
> And fiercely shed intolerable day,"

the door is kept wide open on the hook, and a hanging curtain takes its place, allowing air to play in, while the light admitted can be modulated at will. The testing table is arranged with all the necessary instruments, and the insulation of all the various pieces is very carefully ensured. The table is covered with sheet gutta-percha, and all the insulated wire used in the connections is fixed in position with small gutta-percha straps or staples. Besides the testing table there is usually a folding writing table and chair, also a nest of drawers for keeping small tools, spare jointing materials, galvanometer mirrors and suspensions, &c. The batteries, which may amount to two or three hundred cells, are all ranged in racks underneath the testing table, and the connections brought to commutators, by which the battery power can be easily changed as required. There is also a library and a comfortable lounge along one side of the room; this sanctum of the electrician being generally a cosy little place, where are spent some of the many hours passed at sea while steaming from one position to another. In bad weather it is a welcome retreat, and, where you can, reclining

> "With sidelong eye look out upon the scene,"

though it may be in no such satisfied frame of mind as Wordsworth's dreaming man.

It will be understood that on starting the coiling of cable picked up, the end was left sticking up at the side of the tank so as to be accessible for connecting on an insulated leading wire to the testing-room. This insulated wire remains so connected until the first cut takes place, when it is shifted on to the new end. In the testing-room the end of this wire is connected to the testing terminal during the ship's tests, or is shifted over to a terminal on the speaking connections when it is desired to communicate with the shore. Also in the periods of time during which it is arranged for the shore to test, the end is either freed or earthed by the ship as required.

A set of testing and speaking connections, such as fitted in the testing-room of a repairing steamer, is shown in Fig. 38, the testing galvanometer, speaking mirror, lamps, and scales being shown in elevation, and the testing apparatus and connecting wires in plan. The apparatus and arrangement of connections vary somewhat in different ships, but are generally arranged in such a manner that by simply changing one or two plugs the cable can be tested by bridge or deflection methods. The galvanometer used on all ships is the marine galvanometer of Lord Kelvin, which, enclosed in a thick soft-iron case, is perfectly screened from external magnetic influences occasioned by the motion of the iron-built ship. In the set of connections here shown, which were so arranged on board the cable-ship "Agnes," the cable is connected to the terminal S for speaking to the shore, and to the terminal X for testing, the commutator plugs P P and the plug B being put in for bridge test, and the plug D being put in (the others being removed) for deflection test. In this set the bridge ratios of 10 to 10,000 ohms are in a separate box, and the adjustable resistance is made up in the dial form, which has the advantage of using only one plug for each dial, and does not, therefore, depend on the contacts made by other plugs. The earth terminal in the testing-room is usually connected to the sheathing wires of the cable under test. The deflection test is used on first cutting the cable after grappling, to rapidly show which end has faulty insulation, and is also used continuously during paying out to show that the cable remains perfect, and to detect, should such an untoward event happen, the paying out of a faulty length. The same connections may also be used when measuring the insulation by fall of charge or seeing what amount of capacity there is in

* All rights reserved.

Digitized by Google

the length of cable from ship to shore. From the deflection test connections it will be seen that it is only a matter of a few seconds to change over on to the bridge connections by the plugs. The bridge is used for all practical fault localisation tests, and, with the exception of the Mance test, the balance is obtained to the false zero caused by the polarisation of the fault.

The momentary current of charge referred to above is due to the fact that the cable from the ship to the fault is like a big condenser, and takes a considerable static charge when its conductor is put in connection with one pole of the testing battery—the other pole being to earth. The cable becomes statically charged—that is, considering the two concentric metallic conductors, the internal copper conductor and the outer metallic sheath, there exists between these two surfaces, along the whole length of the cable up to the fault, a charge of a certain quantity of electricity through the insulating material. The rush of current due to this charge is only momentary, but of great strength—that is, a sensitive galvanometer would have to be heavily shunted to keep the throw on the scale at all. But, except when measuring the capacity of the cable, this violent kick or throw is never wanted, and in the various bridge tests it is a decided bugbear. The short-circuit key connected to the galvanometer terminals, as shown in the illustration, is specially provided to short-circuit the galvanometer on the first application of the testing current and prevent this rush of current passing through it. Now small faults polarise so quickly that the testing current cannot be kept on for a longer time than will allow the charge current to pass, and the short-circuit key on the galvanometer is therefore opened after a sufficient time is judged to have elapsed. But it is a difficult matter to judge this time; should it be opened too soon the result on the bridge will be too low, owing to the charging current, while if too late the result will be too high, owing to polarisation of the fault.

Further, the same cause interferes with the correct reading of the false zero. The false zero is the deflection of the galvanometer caused by the polarisation current from the fault itself, and what is wanted is to find the strength of this current which acted during the time the testing current lasted. Now, as the electromotive force of polarisation falls after the battery current ceases, it is clear that the sooner it is observed after the battery key is released the better. In releasing the testing-key the back contact completes the circuit from the conductor of the cable through the galvanometer to the sheathing, which permits the polarising current to flow; but, unfortunately, at the same time the static charge is now given up or discharged, since the two charged surfaces—the conductor and the sheathing—are now united through the instrument. The galvanometer must therefore be kept short-circuited, after the cessation of the testing current, for a sufficient time to allow this discharge to be completely dissipated, or else it will make the false zero falser still. The exact time, which varies from about five or six seconds on lines up to 400 miles, and up to ten or fifteen seconds on lines up to 1,000 miles, is not easy to judge when a fault is under test.

With a single fault making partial earth it generally happens that when tested from the ship at close quarters it can be opened out more with the zinc current and its resistance reduced, so leading to a more definite assigning of its position. Suppose, for instance, that after trying a number of different tests from the moment the ship starts picking-up the fault is estimated to be 3½ miles off. Orders will be given to cut at 4 miles, and when the rotometer shows this length hauled in the cable is cut, generally in tank, and the new end connected up to the testing-room. Tests now may show the fault to be still further away, and orders are given to continue picking up. Tests are now applied again, and this time it is estimated that another half-mile will bring in the fault. The cable is accordingly cut again, but the fault may be still further off. By a test on this fresh end the fault is probably better got at, and, certain that the fault cannot be far from the ship, the electrician gives orders to cut after another mile has come in. This being done, and the new end being connected to the testing-room, he has the satisfaction to find that his low readings have disappeared, and the cable now hanging to the ship is electrically perfect. The fault is, therefore, contained somewhere in the last piece coiled in tank, which is labelled, and shortly afterwards treated to a loop test, spotted, examined, and reported on. Each time the cable is cut the drum is heavily braked and the engine stopped.

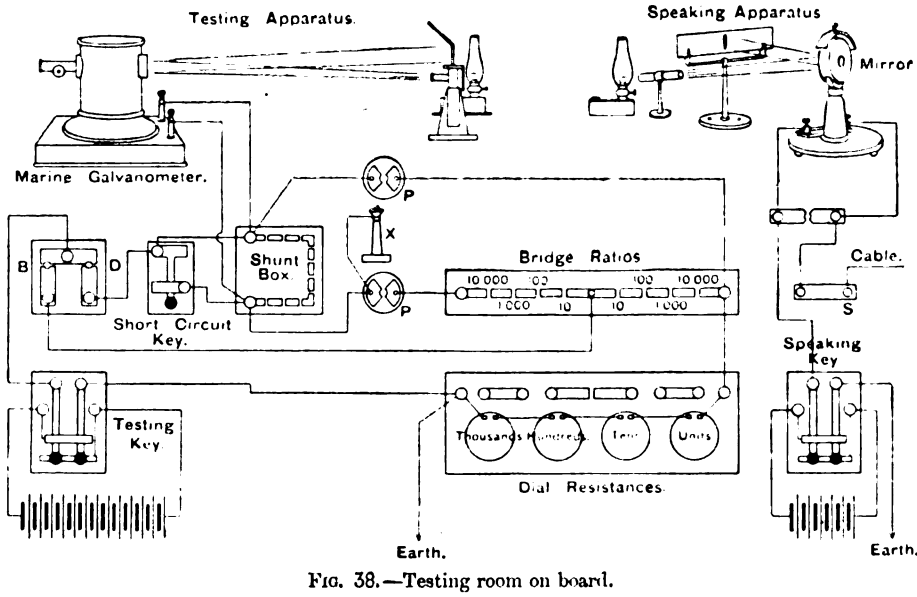

FIG. 38.—Testing room on board.

Very varied successes attend this work of removing faults. Sometimes the first position is close to the fault, at other times it appears close but is really not so; and after testing and cutting, say, five or six times over a length perhaps of eight or ten miles, the fault is at last got inboard. In other cases of less frequent occurrence it may be estimated after one cut has been made at, say, two miles, that the fault is much further off, say, 15 miles. In that case the cable end is buoyed and the ship runs on about 16 miles further and grapples. Having got cable, it is cut and tested, and the good end buoyed. Say the fault is found to lie towards the second buoy. After cutting at three miles, say, the fault is found to be inboard. A good piece is then spliced on and paid out up to third buoy, where the end is spliced on to the end on buoy. Finally, the ship runs back the 16 miles to second buoy, splices on a piece to this end and pays out to first buoy, where the final splice is made. In the case of a break, of course, cable is picked up till the broken end comes on board, and the ship then steams about a mile and a-half further on, lowers grapnel, and after hooking cable, cuts it, buoys the good end and picks up to other end of break. She then runs back to the last buoy, splices on

Digitized by Google

and pays out to the first buoy, where the final splice is made. When, however, there is any such wide difference between the estimated and actual position of the fault as in the foregoing example it is in most cases discovered by the ship upon first cutting in. Before proceeding to buoy or pick up, and while the two ends are on board, several tests will be tried. If the electrician's first test places the fault considerably further on or further back, say, 20 miles, it is a matter of great importance to confirm this by other tests, and if there is a duplicate cable in good condition he will request the end with whom he can communicate to take a loop test. This end accordingly advises the other end to loop his cables. Whereupon the ship joins the two ends, or, as it is called, "puts D F" on board for a predetermined time, say, five minutes. This result may again be confirmed by the ship taking a loop test with the two shore stations looped through. Supposing that these tests all confirm the first and place the position of fault considerably further away, the ship, after advising the shore, permanently splices the cable together again where it was cut, throws the bight overboard and runs on to the newly-estimated position, where she grapples and cuts in as before.

When it is known on board that the fault is removed, the cable end hanging to the ship is at once stoppered, and the end of a sufficient length of good cable (in this case about five or six miles) is got up ready for splicing. The jointer and his mate are on the scene, and commence preparations on the new end to be joined on. The seaward end is not at liberty for a few minutes, as now communication is restored with this end there are several service messages to be sent and received. After the test proving the insulation perfect, the ship calls up the shore and sends a message to this effect to headquarters: "Fault removed (say) 490 miles from ——, now join up and pay out." Also a similar message to the superintendent on shore: "Fault removed, now join up and pay out, free one hour, then look out." The cable is always freed by the shore for one hour during the making of a splice, to allow for tests during and after splice is made. We will now turn our attention to the making of the cable joint and splice.

[**Erratum.**—On page 143 the fourth line of the second column should read "one-twelfth additional weight."]

(To be continued.)

"THE EARTH" ON ELECTRIC RAILWAY CIRCUITS.

In an article in the *Western Electrician* of April 16, Mr. Charles Proteus Steinmetz discusses the question, "Which Terminal shall we Ground in Electric Railway Circuits?" The matter is one of some importance to engineers; and in view of the prognostications in the recent Lane Fox case, as to the difficulties which would arise if an earth return were used for electric lighting circuits, it is not without interest to learn what has actually occurred in practice on electric railway circuits. We therefore reproduce some extracts from Mr. Steinmetz's article:—

In most electric railway systems the circuit is grounded by using the rails as return. It is thus, indeed, not a true earth return circuit, as employed on telegraph lines, because for such large currents as employed in railway propulsion the carrying capacity of the earth is not sufficient to quickly distribute the current. Therefore, a metallic return circuit is always provided by connecting the rails with each other and with a bare underground conductor, which carries the return current, so that the earth forms only a shunt to the return circuit. But, unfortunately, the earth is not a "metallic" conductor, but is an electrolytic conductor. Therefore, for every ampere of current which passes through the ground a rigidly determined amount of chemical action must take place. Considering the large amount of current always circulating in the return wires of extensive railway systems, and the vast surface of rails and conductors exposed to the earth, we cannot wonder that practice proved rapid destruction of return wires and rail bonds by electrolytic action. It became customary, therefore, to connect the negative terminal with the return circuit and the positive terminal with the trolley line. The reasoning which led to this custom was about the following:—If an electric current passes through an electrolytic conductor at the positive terminal, oxygen is developed, which rapidly dissolves all the metals except very few, while at the negative terminal metals or hydrogen are set free, which affords a thorough protection for the negative terminal. Therefore it was thought that by connecting the return circuit to the negative terminal it would be protected against electrolytic destruction.

Suppose the positive terminal connected with the trolley line, the negative with the return wire, and let us follow the path of the current. Leaving the central station, the current flows over the trolley line through the motors to the rails, from rails to return wire, back to the station, while a shunt-current branches off from the return circuit at or near the motor, passes through the ground, and enters the return circuit again in proximity to the power-house. Consequently, the rails and the return wires at and near the motor will be positive against the earth and eaten away by electrolytic action, and near the central station rails and wires are negative against the earth and protected from destruction. Consequently a neutral zone exists where the earth potential is the same as the potential of the return circuit.

Let us connect, now, the negative terminal to the trolley line the positive to the return. Then the whole phenomenon is simply reversed, and the other half of the return circuit is endangered.

Changing the line terminals frequently would not help either, but only damage the whole system of return wires equally. Besides, a change of the line terminals meets with difficulties caused by the necessity of protecting the station against electrostatic discharges from the line; that is, against lightning. This makes it necessary to connect the series coil of the compound generator to the trolley line, so that a disruptive discharge, entering the power station from the line, finds its path obstructed by the heavy self-induction of the series coil, and is thereby forced to jump at the lightning arrester; while, in reversing now the terminals, the series coil of the generator field would be between armature and ground, and such an oscillating discharge would find a free path into the armature, and very likely, not being able to pass from the armature to the ground through the impedance afforded by the series coils, disruptive discharge would destroy the armature. So we see that there exists no possibility of protecting a grounded return circuit against electrolytic action by connecting either the one or the other dynamo terminal to the return circuit; but in either connection half the circuit is protected, while the other half is exposed to oxidation.

If the central station is provided with a large and extensive ground a slight advantage exists in favour of connecting the positive terminal to the return circuit, because in this case a part of the current enters the earth over the ground in the station, and thereby the neutral zone of zero potential is moved nearer toward the station; and if it were possible to make the ground in the station of such a low resistance that it is equal or superior to the ground afforded by the whole return circuit, which is practically hardly possible, the radius of zero potential would coincide with the limits of the power house, and the whole return circuit be protected by throwing all the destructive action upon the ground in the central station. Connecting the positive terminal to an extensive ground in the station, and interposing a suitable resistance between the return circuit and the positive terminal, would bring the return circuit below the earth potential also, and thereby protect it, indeed, by the expenditure of a certain amount of energy in the resistance.

Besides this integral circuit, local electric circuits are formed between the iron rails and the copper conductor, iron and copper forming a galvanic couple. If the positive dynamo terminal is on ground, the line current flows against this E.M.F., and at least occasionally impedes its obnoxious action, while, by grounding the negative terminal, the live current flows *with* the local currents.

Hence, neither by connecting the negative nor the positive terminal with the grounded return circuit, can protection be secured. But in regard to local currents it is more advisable to connect the positive terminal to the return circuit, which practice is also of some advantage if a separate ground in the central station is provided.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, June 24th.

PHYSICAL SOCIETY.

5 *p.m.* Papers to be read: (1.) "Breath Figures." By W. B. Croft. (2.) "The Measurement of the Internal Resistance of Cells." By E. Wythe Smith. (3.) "Units of Measurement." By Mr. Williams.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

MECHANICAL SCIENCE AT CAMBRIDGE.

There is some difference of opinion as to the distinction between scientific education and technical instruction. The practical bearing of pure science on the manufacturing and industrial arts is as evident as the grounding in science which is the foundation of sound technological training. Hitherto the distinction has been tolerably well maintained, but it seems likely to diminish and in many cases to disappear completely. It is because the foundation of engineering, and more especially of electrical engineering, is scientific, that those who are connected with these professions may be expected to take an interest in the teaching of science; but because their aims are for the most part utilitarian, and their work, so far as it is professional, is essentially commercial, there have of late been many expressions of surprise, and even sneers, at the idea that any form of knowledge may be valuable and at the same time useless; the paradox depending merely upon the meaning attached to the word "useless." Rather more than a year ago we gave a sketch of the development of the School of Engineering at Cambridge and made an appeal for the laboratory which it was then proposed to found. On that occasion (*Electrician*, vol. XXVI., p. 668) we quoted from a Report upon this subject, which gave several indications of a change in the University system. Last week we gave an abstract of a Report upon the proposed Mechanical Sciences Tripos, which described pretty clearly the arrangements which are contemplated, and the reasons for the recommendations. The University of Cambridge is officially defined as "a society of students in all and every of the liberal arts and sciences;" and the question at once arises, what are these liberal arts, and why are they so called? There may be, for all we know, a diversity of opinion here, as there is evidently a diversity of purpose; but going back to the origin of the term, we know that the *artes liberales* among the Romans were the higher

Digitized by Google

arts which only freemen were permitted to pursue. These in the Middle Ages were known as the seven branches of learning: grammar, logic, rhetoric, arithmetic, geometry, music, and astronomy; among these may to-day be included philosophy, history, philology, and natural science, though it is only quite recently that the last has been accepted at Oxford. A liberal education is not antagonistic to technical instruction: the former enlarges and disciplines the mind and makes it master of its own powers, irrespective altogether, as the name implies, of the particular business or profession that may be afterwards followed; the latter gives a sound knowledge of the principles of a trade.

The educational value of technical instruction is accidental. No one can intelligently read the elementary chapters of Maxwell's "Theory of Heat," and parts of the writings of Huxley, Lyell, Darwin, and Tyndall, without deriving educational benefit from them on account of their literary excellence, quite apart from the subject matter. An interesting claim for the educational value of science is made by President Walker, of the Massachusetts Institute, in the last number of the "Technology Quarterly": "The sincerity of purpose and the intellectual honesty which are bred in the laboratory of chemistry and physics, stand in strong contrast with the dangerous tendencies to plausibility, sophistry, casuistry, and self-delusion which so insidiously beset the pursuits of metaphysics, dialectics, and rhetoric, according to the traditions of the schools. Much of the training given in college in my boyhood was, it is not too much to say, directed straight upon the arts which go to make the worse appear the better reason. It was always an added feather in the cap of a young disputant that he had won a debate in a cause in which he did not believe. . . . Contrast this with the moral and intellectual influence of the studies and exercises we are considering. The student of chemistry or physics would scarcely know how to defend a thesis which he did not himself believe. The only success he has hoped for has been to be right." An ingenious argument, more favourable to science than unfavourable to classics.

The reason for the establishment of a Tripos which thus ranks mechanical science with such important branches of knowledge as classics, mathematics, history, and natural science is plainly stated in the Report which we published last week. The present ordinary degree in "Mechanism and Applied Science" in which no honours are given, is "wholly inadequate for the more able students;" and "the want of such an examination deters men from coming to Cambridge who would otherwise be likely to profit by the training in science which the University offers." To this it may be answered that an able student, if he can afford the time, had far better make use of the opportunities afforded for a thorough acquaintance with natural sciences generally, or perhaps of physics in particular, by the existing Tripos. If he, and those who are at present deterred from going to Cambridge, want to learn a profession, they ought to go to the establishments which have been founded for that very purpose. It is probable that the University will suffer if it holds out baits to men who would have hitherto gone to technical colleges, and for whom the University as a university otherwise offers no attraction. The difference between pure mathematics and applied or mixed mathematics is a mere nothing compared with the difference between theoretical thermodynamics and slide-valve setting, or between the adjustments of a spectroscope and of a theodolite. The fact that the one of these is primarily an instrument for scientific research, and that the other is the tool of a surveyor, places a wide gulf between them. If the progressive party have their way, the University seems likely to attract a different class of man, who will look to the utility of all he learns, and will work with a distinctly commercial aim, perhaps under professors who take out patents! Let those who induct their pupils into trades, scientific or otherwise, foster the commercial spirit which is essential to commercial success, but, for heaven's sake, may Cambridge never merit the reproach of becoming a university of shopkeepers!

If the Tripos is really confined strictly to mechanical science as science, and not as technical instruction which is not necessarily scientific or educational, no harm will be done; but the very fact of its extreme utility and practical application will make it extremely difficult to adhere to this ideal. There will, in fact, be (according to modern paradoxy) a danger of teaching something useful. "What in the name of the Bodleian," writes Augustine Birrel, "has the general public to do with literature?" and what in the name of the Cavendish, may it be asked, have the "liberal arts and sciences" to do with most of the subjects for the "practical examination" of the proposed Tripos? Practical examinations in pure science are of course indispensable; but some of the subjects, for example, the measurement of the modulus of elasticity of materials, were set for practical examination work with a cathetometer in the Cavendish laboratory twelve years ago. The expressions "practical" and "theoretical" cannot be so easily applied to classics. Theory there may mean philology, and practice, translation and composition; or theory may be used for the study of ancient philosophy, and practice may include a course of conversational lessons in modern Greek, followed by a Cook's tour in the Peloponnese and a long vacation spent in comparative scaphology and general oryctics.

The use of a practical examination in physical science is to show whether a student is conversant with laboratory apparatus and has an intelligent appreciation of and acquaintance with the methods of experiment and measurement, and has nothing to do with the application of knowledge to some utilitarian or remunerative end. The more opportunities that are given for the study and development of pure science at Cambridge, the better for the science of this country and of this age; and physical science is not behind the other important branches of knowledge which form the subjects of the Natural Science Tripos. There is indeed room for wide expansion; for while chemistry and physiology have numerous important subdivisions, and a whole range of subjects such as mineralogy, crystallography, palæontology, are included under geology; physics, which cover mechanics, heat, sound, light, magnetism, and electricity, is the most comprehensive of them all. Nearly the whole of the really scientific subjects of the proposed Mechanical Sciences Tripos fall under the head of Mechanics as the first section of Physics. Students going in for honours in Natural Science are expected to specialise in one subject; and there seems no reason why in so wide a one as physics, special attention should not be paid to one section, and opportunity afforded by the examiners to allow a first class to be taken mainly in this important subject, together with any one other, say electricity. This would not lower the standard of the educational system; it would meet most of the arguments which have been put forward in support of what is really an Engineering Tripos; and while the present ordinary course in Mechanism and Applied Science would benefit largely by the development of the laboratory and higher classes, there would be no danger of introducing at Cambridge, under the guise of another science Tripos, an imitation of, or a competition with, the technical colleges which serve so useful and so different a purpose in other parts of the country.

THE USE OF WATER-POWER FOR ELECTRICAL PURPOSES.

BY NORMAN F. WILSON.

(*Continued from page 146.*)

Having briefly dealt with the questions of measuring water, the efficiency of turbines and waterwheels, and the flow of water in pipes, we shall now describe a few of the more prominent types of turbines, and discuss their suitability for electrical work.

There are five different types of turbines now in the market, any one of which is greatly superior to the old-fashioned waterwheel for nearly every description of work, and is certainly so for driving dynamos. The five types are:—I., Inward flow; II., Outward flow; III., Axial flow; IV., Mixed inward and axial flow; V., Tangent.

In inward flow turbines the water is directed by guide blades against the circumference of the wheel, and leaves it at the centre. In outward flow turbines the guide passages are inside the wheel, and the water leaves at the circumference. In axial flow turbines the water enters and leaves the wheel in a direction parallel to the axis or shaft on which it revolves. In turbines of mixed flow the guide blades are outside the wheel and direct the water against its circumference as in type I.; but instead of leaving the wheel in the centre the water is turned round and leaves as in type III. In a tangent turbine there are no guide blades, the water being directed against buckets on the periphery of the wheel through a nozzle.

The chief points to be taken into consideration when choosing a turbine are:—Economy of water. Simplicity of construction. Regularity of speed and the readiness with which it can be adjusted to varying quantities of water.

Two other important considerations are, whether they can be placed above the tail water and work by suction, and their liability to be backwatered in time of flood. All the turbines we shall describe have fulfilled the first of these conditions, are of simple construction, and are not likely to get out of order.

Every turbine has a tendency to race when the load is taken off, but the design of the inward flow type renders it less liable to extreme fluctuations of speed than the outward flow because the centrifugal force of the wheel to a certain extent checks the flow of the water, whereas in the outward flow it has the reverse effect.

Types I., III., and IV. may be placed at any height not exceeding 30ft. above the tailwater level, using the fall below the wheel by suction as efficiently as if it were acting by direct pressure above. That is to say, that the pull of the column of water standing in the suction pipes below the wheel causes the water entering it to move as rapidly and with as much kinetic energy as if it had the whole fall acting by pressure.

This may be easily illustrated by the following simple experiment. Fill a glass tube three or four feet long with water, and having covered up the top end tightly with a finger, place it upright in a basin of water. The water will, of course, stand in the tube, and there will be a pull on the underside of the finger equal to the weight of the water supported. In turbines working by suction the action is precisely similar. The whole pressure of the air is on the top of the water above the wheel, whilst below there is only this pressure, less that taken to support the water in the suction tubes.

It is not usual in practice to place a turbine more than about 25 feet above the tailwater level, as it necessitates the glands being very tightly packed. There is no loss of power when a turbine of any one of these types is working by suction, provided the suction tubes are kept air tight.

When choosing a turbine this question must not be neglected, since one which can utilise part of the fall by suction is, as a rule, more convenient than one which cannot. The wheel is keyed into a horizontal shaft which has all its bearings above water, and from which the power can be transmitted by belting direct to the dynamo without any gearing.

Types I., III., and IV. are not affected by back water when the water rises in the tail race in time of flood, except in so far that they give less power on the reduced fall.

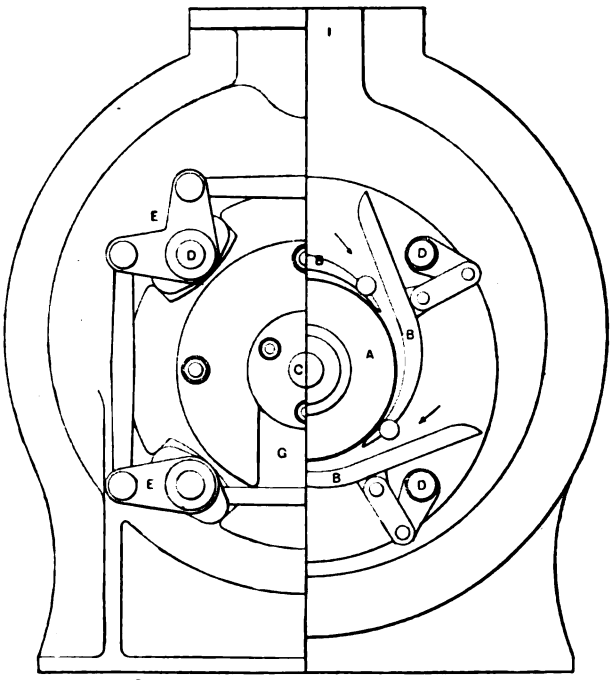

FIG. 2.—Vortex Turbine, end view, part section.

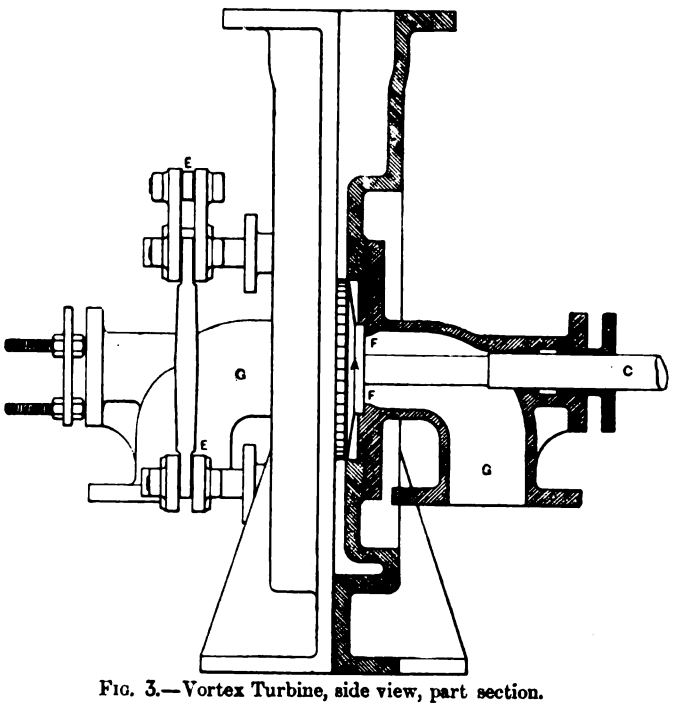

FIG. 3.—Vortex Turbine, side view, part section.

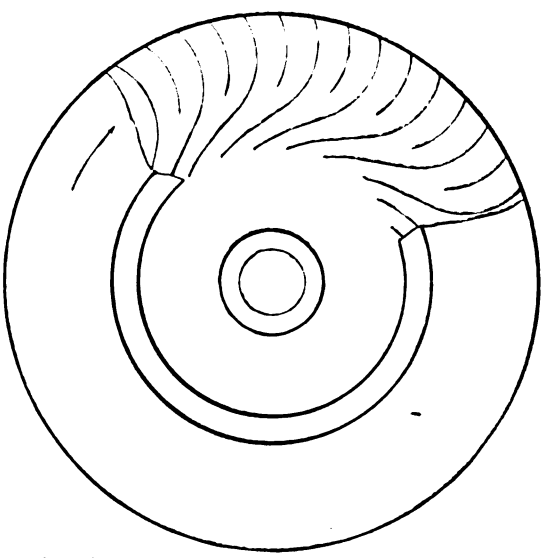

FIG. 4.—Wheel of Vortex Turbine, on larger scale.

Digitized by Google

We shall now describe one or more well-known varieties of each type in the order enumerated above, pointing out their chief characteristics and when each type may be most suitably applied.

Inward Flow Turbines.

We shall take the vortex turbine as our example of this class as it is the first that was constructed and is much used in electrical installations.

The vortex was invented in 1851 by the late Prof. James Thomson, of Glasgow, and since that date has been placed on falls varying from 2ft. 9in. to over 500ft; it has in fact been effectively applied to almost every height of fall that is available in this country.

Figs. 2, 3, and 4 shows the general construction of this turbine very clearly. The water enters an outside chamber through the inlet I, whence it is directed by the guide blades B against the revolving wheel A. The smaller sizes of wheel are made of brass and the larger of wrought steel tenoned and rivetted together. The wheel is divided in the middle by a centre plate which is screwed or keyed into the shaft C. The water leaves the wheel by the central eye, half of it passing out at each side, through the suction pipes G G., which are provided with glands for making an airtight joint. The wheel A makes a practically watertight joint with the suction pipes at the joint F. The vanes of the wheel are very numerous and are curved in the manner shown in Fig. 4. Each wheel is designed separately to suit the precise conditions under which it has to work.

In order that the turbine may be used with varying quantities of water, the guide blades B (Fig. 2) are pivoted close to the point and may be opened or closed at pleasure by means of the bellcranks and links shown in the illustrations.

This is a very effectual method of obtaining the best efficiency from a small supply of water, because, even when the turbine is working at half or quarter gate, the water is conducted to the wheel through long smooth and continuous channels, and is not abruptly checked in any part of its course.

According to many high authorities the inward-flow type of turbine is the best for almost every situation, since in it the water is supplied to the wheel at the circumference, where its speed is greatest, and, having done its work in driving it round, leaves at the centre at a minimum velocity.

The speed of the vortex wheel at the circumference is approximately equal to the velocity due to half the head. Thus, in a turbine working under a fall of 20 feet the speed of the periphery of the wheel is equal to the velocity of a jet escaping under 10 feet head.

When a portion of the load is taken off and the wheel begins to run faster than this speed, the extra centrifugal force which it generates checks the water from flowing into it so rapidly as it otherwise would do; if, on the other hand, a heavier load is put on and the wheel begins to run slowly, the centrifugal force is diminished and more water is admitted. This inherent tendency to self-government is of great value.

On low falls up to 8 or 10ft., the wheel is generally placed horizontally with a vertical shaft; the power is transmitted by a pair of bevel wheels to the horizontal shaft from which the dynamo is driven. The bottom end of the shaft is supported by a lignum vitæ pivot, which can be raised, as it wears, by a lever and rod. A wooden pentrough carrying strainer plates for stopping leaves, stones, &c., is placed above the supply pipe. These plates must always be kept clear. The foundations for the turbine are very simple, consisting merely of three large stones or blocks of masonry. With a higher fall the turbine wheel is usually placed in a vertical position on a horizontal shaft, from which the dynamo can be driven by a belt. As the water leaves the wheel in equal quantities at each side the wheel is always balanced, and there is no tendency to end thrust, which is an inconvenience in many turbines when placed on a horizontal shaft. When the fall is high, say over 50ft., the turbine can generally be coupled end on to the dynamo, and the whole be mounted on to one bedplate. As this arrangement dispenses with belting entirely and saves a great deal of space, it is the best when it can be adopted.

(To be continued.)

MAGNETIC PROPERTIES OF LIQUID OXYGEN AND AIR.*

BY PROF. DEWAR, LL.D., F.R.S.

After alluding to the generous aid which he had received both from the Royal Institution and from others in connection with his researches on the properties of liquid oxygen, and to the untiring assistance rendered him by his co-workers in the laboratory, Prof. Dewar said that on the occasion of the commemoration last year of the centenary of the birth of Michael Faraday he had demonstrated some of the properties of liquid oxygen. He hoped that evening to go several steps further, and to show liquid air, and to render visible some of its more extraordinary properties.

The apparatus employed consisted of the gas engine downstairs, which was driving two compressors. The chamber containing the oxygen to be liquefied was surrounded by two circuits, one traversed by ethylene, the other by nitrous oxide. Some liquid ethylene was admitted to the chamber belonging to its circuit, and there evaporated. It was then returned to the compressor as gas and liquefied, and thence, again, into the chamber as required. A similar cycle of operations was carried out with the nitrous oxide. There was a hundredweight of liquid ethylene prepared for the experiment. Ethylene was obtained from alcohol by the action of strong sulphuric acid. Its manufacture was exceedingly difficult, because dangerous, and as the efficiency of the process only amounted to 15 or 20 per cent. the preparation of a hundredweight of liquid was no light task. The cycle of operations, which, for want of time was not fully explained, was the same as that commonly employed in refrigerating machinery working with ether or ammonia.

The lecturer then exhibited to the audience a pint of liquid oxygen, which by its cloudy appearance showed that it contained traces of impurity. The oxygen was filtered, and then appeared as a clear transparent liquid with a slightly blue tinge. The capillarity of liquid oxygen, although much less than that of water, was, he stated, still considerable.

Reference was then made to a remarkable experimental corroboration of the correctness for exceedingly low temperatures of Lord Kelvin and Prof. Tait's thermo-electric diagram. If the lines of copper and platinum were prolonged in the direction of negative temperature they would intersect at – 95° C. Similarly, the copper and palladium lines would cut one another at – 170° C. Now, if this diagram were correct, the E.M.F. of the thermo-electric junctions of these two pairs of metal should reverse at these points. A Cu – Pt junction connected to a reflecting galvanometer was then placed in oxygen vapour and cooled down. At – 100° C. the spot of light stopped and reversed. A Cu – Pd junction was afterwards placed in a tube containing liquid oxygen, and a similar reversal took place at about – 170° C.

The next experiment showed that liquid oxygen presented great resistance to disruptive electric discharges. A tube filled with the liquid was placed in parallel with the discharge knobs of a Ruhmkorff coil, electrodes $\frac{1}{10}$th mm. apart being plunged into the tube. Almost all the sparking took place in air.

The spectrum of liquid oxygen was then discussed. The A and B lines of the solar spectrum had generally been attributed to absorption by the oxygen of the atmosphere. Last year M. Janssen went up Mont Blanc to test the matter, and found that the higher he went the fainter these characteristic oxygen lines became. Now, a question of great scientific interest was, were these lines maintained through the change of state from gas to liquid? Experiment showed that the lines existed in the liquid exactly as in the gas.

The next experiment was the direct liquefaction of atmospheric air under the ordinary pressure of the atmosphere. A tube containing liquid oxygen was connected to an exhaust pump, and the oxygen was evaporated at a lower and lower temperature. An inner tube was left open to the air, and in a short time was filled with liquid air, which exhibited at first

* Abstract of Friday Evening Discourse delivered at the Royal Institution, June 10, 1892.

Digitized by Google

all the characteristics of atmospheric air and none of those of liquid oxygen. It was curious at first sight, said the lecturer, to find the two components of atmospheric air liquefying together, and not the oxygen first and then the nitrogen. This was due to the very different pressures at which the two gases were; the volume of nitrogen being four-fifths of the atmosphere and oxygen one-fifth. But once liquefied atmospheric air behaved in quite another manner. Nitrogen then boiled off first, because it had a boiling point 10° below that of oxygen. Hence, on first production, liquid air had none of the properties of oxygen; but as the nitrogen evaporated out it behaved more and more like oxygen, and finally lighted glowing matches, and exhibited the characteristic spectrum of oxygen. When placed between the poles of Faraday's electro-magnet freshly liquefied atmospheric air was seen in that case to act as a quantity of liquid oxygen, the whole mass adhering to the poles when the magnet was energised. Experiments showed that liquid atmospheric air, although containing four-fifths of its volume of nitrogen, did not have the extraordinarily high electric resistance of liquid oxygen modified in the slightest degree.

Coming then to the magnetic properties of oxygen the lecturer alluded at some length to the laborious researches of Faraday and Becquerel. In 1847 Faraday announced that oxygen was + or paramagnetic in regard to all the gases he had experimented with (air, carbonic acid, hydrogen, coal gas), but he was uncertain what medium should be taken as zero. Later on in 1849 Edmond Becquerel came to the conclusion that oxygen was truly magnetic with reference to air and vacuum. On Becquerel's scale the magnetic susceptibility of iron came out at 1,000,000, and that of oxygen at 377. When liquefied the magnetic susceptibility of oxygen rose to 1,000. Liquid oxygen was poured into a cup of rock salt placed between the poles of Faraday's electro-magnet, and on the coils being circuited the mass of liquid oxygen was seen to be lifted up and plastered against the poles until the circuit was broken, when it immediately collapsed. A U-tube containing liquid oxygen was next placed between the poles, and on the magnet being excited the liquid was sucked out. A ball of cotton wool moistened with the liquid adhered to the poles when they were magnetised. A crystal of sulphate of iron behaved in the same way after cooling by immersion.

In conclusion, the lecturer said that he had originally started on his researches interested only in the chemical side of the question. In Mendeljeef's classification the successive sets of the elements were alternately para- and diamagnetic. Now fluorine was very close to oxygen, and it was to be anticipated that fluorine would be found to be also powerfully magnetic. Then, again, there was great interest for the chemist in the chemical behaviour of bodies at low temperatures. Bodies which had violent chemical affinities under ordinary circumstances had none whatever at these low temperatures. At − 200° C. the molecules of oxygen had only one-half of their ordinary velocity and had lost three-quarters of their energy. It had seemed to him, therefore, that at these temperatures we approached the death of matter as we knew it. But perhaps he had gone a little too far, and ought not to have confined his attention to contact chemical action, and he wished to limit his previous statements on the subject. The reason which had led him to modify his views was that chemical action was still brought about at these low temperatures by radiant energy from the outside. Could we produce chemical action on a photographic plate at − 200° C.? We could, as might be seen by the view of the plate thrown on the screen, which showed that the ultra violet rays passed through liquid oxygen and did their work. From the physiological point of view also low temperatures had great interest. The spores of micro-organisms were destroyed by elevation of temperature. Were they equally destroyed by reduction of temperature? No! Pieces of putrefying materials were subjected to a temperature of − 200° C. for one hour, and commenced to putrefy on being restored to the ordinary temperature after a few days. Seeds cooled to − 200° C. afterwards fructified and developed. This lent support to a suggestion once put forward by Lord Kelvin, their chairman that evening, that life might well have been introduced into this world from another planet on the back of a meteorite.

THE BRILLIÉ METER.

Motor meters may be divided into two classes: in the one, an armature, or its equivalent, carrying the current to be measured, revolves in a permanent field, and is retarded by a force proportional to its velocity; and in the other the field varies with the current, and the retarding force varies as the square of the velocity. The Brillié meter belongs to the former class, but the motor does not carry the main current. In both classes of meters the friction of the motor, consisting of initial or static friction and of mechanical friction, must be compensated for as in the Ferranti, or masked as in the Perry meter. In this instrument the friction of the meter introduces no error, even at small loads, and only consumes a certain amount of energy. The mechanism consists of three parts—a watt-meter dynamometer with a suspended coil in a shunt circuit, a motor also in a shunt circuit, and a set of resistance coils with movable contacts.

The essential feature of this meter is the method by which the motor is regulated, by the insertion of resistances in series with it. This is effected in the following manner:—A disc of copper is suspended below the movable coil of the dynamometer, and is embraced by a system of permanent magnets, somewhat similar to those which retard the motion of the copper disc in the Elihu Thomson meter. This system of magnets is set in rotation by the motor, and the effect is to drag the copper disc back, and thus to bring the suspended coil into the zero position. A projecting arm from the suspended dynamometer coil engages with a lever which puts the resistance into circuit in three different arrangements. The wattmeter coil is thus kept in frequent oscillation, since the speed of the motor is not maintained uniform, but on the average at such a speed that the dynamometer coil remains in equilibrium. As the different contacts are made the motor receives impulses; but by its momentum it cannot respond quickly to these, and, therefore, on the average records the value of the current. The meter is sensitive, since the initial current required to start it is only that which is needed to swing the dynamometer coil round to make the first contact. This starts the motor, and this in turn drags the copper disc round, and if the current is only a small one, breaks the circuit at once. We understand that the energy absorbed by the shunt coils is about $\frac{1}{1000}$ of the total amount registered. The meter is suitable for alternate as well as direct currents, and has no frequency errors.

THE MEASUREMENT OF ILLUMINATION.*

The following article, correspondence, and editorial reply have appeared in *Industries* upon a subject touched on in the "Notes" on the first page of our issue of May 20th.

One of the most backward branches of measurement is photometry. Certainly innumerable photometers have been invented, and photometers are generally much more accurate than standards of light. Apart from designing photometers, however, little has been done in the study of illumination. Mr. Trotter's Paper, recently read before the Institution of Civil Engineers, of which an abstract appeared in our issue of the 13th ult., deals with the whole subject in a clear and scientific manner. In particular he called attention to the common confusion of the terms "light" and "illumination." We have only one objection to make, and that is to Mr. Trotter's "candle-foot" as the unit of illumination. If a unit of the sort be needed, it should be called a candle per square foot, not a candle-foot. The illumination of a surface is found by dividing the candle-power of the source of light by the square of the distance from the source, not by multiplying. A compound name like "candle-foot" always denotes multiplication, as in pound-degree, foot-pound, volt-ampere; while "per" denotes division, as in mile per hour, pound per square inch. Mr. Trotter argues that everybody knows that illumination varies inversely as the square of the distance, so that candle-foot cannot produce any confusion. But why wantonly call a thing by a wrong

* From *Industries* of May 27th and June 3rd.

Digitized by Google

name? It would be just as sensible to speak of a pressure of 100 inch-pounds. Electricians are already inaccurate in some of their phrases; for instance, insulation resistance is frequently given in megohms per mile instead of in megohm-miles; and, in spite of M. Hospitalier, who is the soul of method in these things, some people give specific resistances in microhms instead of in microhm-centimetres.

Mr. Trotter takes the illumination due to a standard candle one foot away as unit illumination. The unit of light is then taken as the light falling on a square foot which is one foot away from the candle. This leads to the curious result that a candle gives a total light of 4π, or $12\frac{1}{2}$ candles. This seems strange to those who are not acquainted with the conventional mathematical treatment of problems in attraction, hydrodynamics, heat, and electricity. The treatment of light is exactly analogous, and so Mr. Trotter's candle which gives a light of $12\frac{1}{2}$ candles is perfectly correct. Light is on all fours, for instance, with electrostatic induction, so that illumination is a flux, and is thus measured in candles per square foot or some analogous expression. We sincerely trust that, for the sake of the peace of mind of future systematisers, Mr. Trotter will not bring the candle-foot into use, but will give us the more accurate, if cumbrous, "candle per square foot" instead.

SIR: To reply fully to the short article, in which you criticise some points raised in my recent Paper on illumination, would occupy more of your space than I can ask, and more of my time than I can at present give. A whole chapter of the science of optics yet remains to be written, and one which will prove to be of great practical value.

You would have better reason to object to "Mr. Trotter's 'candle-foot' as the unit of illumination" if I had indeed originated the unit or its name; but I understand that Mr. Sugg used it 30 years ago, and I never imagined for a moment that I was concerned with so serious a responsibility as the creation or naming of a new unit. French writers who have paid some little attention to the subject of illumination, have used the "carcel-metre" and "bougie-metre" with, in my humble opinion, such lucidity, that in spite of the protests of M. Hospitalier* and M. Weissenbruch,† I ventured to use the "candle-foot" as the British equivalent. You say, in the first place, that the unit should be called a "candle per square foot." This subject is complicated by the frequent introduction (or suppression) of unity and of its square. To be exact, if clumsy, I would rather say, "a candle per foot squared," for by "foot" I mean most distinctly the distance of the candle from the illuminated surface, and not the square root of an illuminated area. To speak of so many candles or parts of a candle per square foot is likely to lead to much more serious errors.

Mr. Preece's rule of one 16 c.p. lamp per 64 square feet of floor is sound only when it is carefully coupled with the condition that the lamp is 8ft. from the surface to be illuminated. If I specify that the average illumination of a hall is to be $1\frac{1}{2}$ candle feet, I say that nobody of ordinary intelligence can imagine that $1\frac{1}{2}$ candles at 1ft. is the same thing as 1 candle at $1\frac{1}{2}$ft.; and that should any doubt arise as to which of these is intended, reference need only be made to the unit—a candle-foot—the specified illumination being $1\frac{1}{2}$ times that unit. How to produce that illumination by the proper distribution of lamps of the necessary power, the name pretends neither to suggest nor to explain. But if the expression "$1\frac{1}{2}$ candles per square foot" be used, a person of intelligence might easily fall into the grave error of reckoning up the surface to be illuminated as so many square feet, and then apportioning $1\frac{1}{2}$ c.p. to each square foot, placing the lamps at any height or distance. He would only be justified in neglecting the height of the lamps if there were an indefinitely great number of them, and an indefinitely great area of illumination.

I admit that some little intelligence is needed to understand the "candle-foot," and agree that, as a rule, compound names denote multiplication. But you say that "it would be just as sensible to speak of a pressure of inch-pounds." There is, however, this important difference, which depends upon the meaning of the term "foot" in the expression "candle-foot," as denoting distance and not area. The "foot," as I have already claimed, is here the measure of a distance. The intensity of the illumination *depends on that distance*. An intensity is composed, it is true, of two factors—something divided by an area; but in the expression "candle-foot" I assume that the area is suppressed, and that the illumination is considered only at a point. The intensity of illumination can be measured in a more roundabout way by total light per square foot, but I contend that it is more simple to take simple candle-power and distance, thus avoiding the 4π difficulty.

* *L'Electricien*, Vol. XXX., page 521 (August 17, 1889)

† *Ibid.*, page 649 (October 12, 1889).

The comparison with "inch-pound" is, I consider, unfair, because the pressure does not depend in any way upon a distance, but is fully expressed by pounds per square inch. May I explain the suppression of the area by an analogy, a hydraulic analogy, so dear to electricians, and, as usual, misleading if pressed too far? There are three different ways of measuring rainfall. I neglect the time and deal only with the intensity. We may reckon it in gallons per acre; three dimensions of water, and two dimensions of land. Or we may take square feet of water per mile of country. The water in a river is commonly measured thus in square feet of vertical section across the stream. That is, two dimensions of water and one of horizontal length. Or we may reduce the dimensions once more, and take inches of water on a point—that is, one dimension of water and no dimensions of land. It may be argued that you cannot measure a quantity of water by linear inches, and *à fortiori*, you cannot measure a quantity of water per unit area in that way, and that dimensions which are necessary for the intelligible expression of a quantity should not be suppressed. M. Hospitalier has suggested the expression "carcel à 1 metre" for "carcelmetre," and I should very much prefer a "candle-at-a-foot" to "candle per square foot" or a "candle per foot-squared." The sole argument in favour of the "lux" as a name for this unit is that it obviates this ambiguity. I should like to see a better name, but it should be self-explanatory.

I must object to taking the unit of light "as the light falling on a square foot which is one foot away from the candle" unless the word "everywhere" be inserted before the words "one foot," showing that the square foot is part of a spherical surface surrounding the candle. From this the 4π paradox arises. But I venture again to differ with your remark that "this leads to the curious result that a candle gives a total light of 4π or $12\frac{1}{2}$ candles. Total light is the product of candle-power into a solid angle. A solid angle is measured by the area of a sphere (of unit radius) which is intercepted. To be accurate, one must say that a candle gives a total light of 4π candle-power. Some very interesting results follow from this, but I cannot enter upon them in this letter, which has already trespassed greatly on your space. To this measure total light by candle-power is a roundabout expedient, but it may be compared with the expression horse-power-hour, which is more convenient than 1,980,000 foot-pounds, or 2,685,860 joules, although it is tautological.

Total light may be measured in "candles," since it is absurd to say that a candle gives a light of $12\frac{1}{2}$ candles. The total light of 1 candle is, of course, 1 candle, and 1 candle = 4π c.p., assuming unit radius and solid angle.—Yours, &c., A. P. TROTTER.

The following editorial note was appended to this letter:—

[Mr. Trotter argues that the foot in "candle-foot" refers specifically to the distance; yet he gives inches of rain as an analogy. Here the inches have nothing to do with the distance from any source. If light accumulated on the surface till it lay a foot thick in a given time, Mr. Trotter might measure illumination in feet per year, but not in candle-feet. He might have found a much better analogy in electric or magnetic displacement which can be given as a length, but not as the product of a length and quantity, or length and strength of pole. Induction might be measured in lines per centimetre squared as well as in lines per square centimetre. But such a way of taking it, though not admissible, is unusual. Mr. Preece's rule is not to the point. What he means is, doubtless, a quarter of a candle per square foot. We are still unable to see that it is right to give a quantity a wrong name and trust to people's intelligence to know it is wrong. To specify $1\frac{1}{2}$ candles per square foot is perfectly definite, and Mr. Trotter's statement that this might lead to apportioning $1\frac{1}{2}$ c.p. to each square foot, placing the lamps at any height or distance, seems to show a confusion in his mind between candles themselves and the light they give. What we think Mr. Trotter fails to realise is that the "dimensions" are wrong in candle-foot. When we mentioned a square foot a foot away from the candle, we did not mean that some of the surface was some other distance off. This is the ordinary method of finding a solid angle of unity. We are not sure whether by "candle" Mr. Trotter means a wax cylinder with a wick or a flow of light. If he means the former a "candle-foot" is a very curious object; if the latter, which is the way we have used it, of course, a candle gives a light of 4π candles. If candle-power is light, then we consider "candle-power per square foot" is the correct unit. Mr. Trotter quotes authorities who agree with him, but there is really no such thing as authority in science. Mr. Trotter may be sinning in good company; what grieves us is that he seems anxious to go on sinning.]

THE LAUFFEN-FRANKFORT TRANSMISSION.

The following information with regard to the results obtained by the testing committee is furnished by the Council of the Frankfort Exhibition. The work of the committee consisted in testing three sets of plant.

The first was that put down by the Allgemeine Elektricitäts Gesellschaft, of Berlin, in conjunction with the Maschinenfabrik Oerlikon for transmitting 300 H.P. from the Wurtemburg Portland Cement Works at Lauffen, on the Neckar, to the Exhibition, a distance of 109 miles. The measurements were made by Prof.

Digitized by Google

Dietrich, Dr. Feussner, Dr. Heim, Dr. Kopp, Messrs. Nizzola and Schmoller, Profs. Stenger, Teichmann, Voit and Weber. Table I. shows the results obtained. It is to be noted that column 12 gives the efficiency expressed as a percentage ratio between the energy consumed by the lamps at Frankfort and that delivered by the turbines at Lauffen. The measurements taken at Lauffen, which were carried out under Prof. Killter and Councillor Lindley, with the view of obtaining the efficiency and other interesting points with pressures of 25,000 and 30,000 volts, will be published later on with the report on the Exhibition.

The second plant reported on consisted of a 20 H.P. engine in the Palmengarten, which by means of a high-pressure continuous current drove a motor in the Exhibition at a distance of 1¼ miles. This was put down by the Deutsche Electricitätswerke of Aachen (Messrs. Garbe, Lahmeyer and Co.). In this case the measurements were taken by Prof. Brauer, Dr. Wirtz, Messrs. Friese, Stapelfeldt and Cesar, and the results are given in Table II. Column 12 in this table gives the efficiency reckoned as the ratio between the brake horse-power developed by the motor, and the whole output of the machine at the Palmengarten. The resistance of the conductor was 5·9 ohms.

On the third installation, carried out by Messrs. Lahmeyer, of Offenback, no results are yet obtainable.

Full details of all these tests, and the instruments used, &c., will be published as soon as the heavy labours of the committee are concluded.

ON THE CHANGES PRODUCED BY MAGNETISATION IN THE LENGTH OF IRON AND OTHER WIRES CARRYING CURRENTS.*

BY SHELFORD BIDWELL, F.R.S.

The changes of length attending the magnetisation of rods or wires of iron and other magnetic metals which were first noticed by Joule† in 1841, and have in recent years formed the subject of many experiments by myself,‡ have been found to be related to several other phenomena of magnetism. Maxwell§ has suggested that they sufficiently account for the twist which is produced in an iron wire when magnetised circularly and longitudinally at the same time. The resultant lines of magnetisation, as he points out, take a spiral form; the iron expands in the direction of the lines of magnetisation, and thus the wire becomes twisted. Professor G. Wiedemann, however, to whom the discovery of the magnetic twist is due, appears not to be satisfied with this explanation, believing the effect to be caused by unequal molecular friction.

The subject of magnetic twists has been very fully and carefully investigated by Prof. C. G. Knott; and in a Paper published last year in the *Transactions* of the Royal Society of Edinburgh (Vol. XXXVI., Part II., p. 485), he indicates many details in which the phenomena af twist closely correspond with those of elongation and retraction. Assuming their essential identity, and noting that "an increased current along the wire affects the points of vanishing twist in a manner opposite to that in which an increased tension affects it," Prof. Knott is "inclined to conclude that the pure strain effects of these influences are of an opposite character." Now, since the magnetic elongation of an iron wire is known to be diminished by tension, the remark above quoted amounts to a prediction that in an iron wire carrying a current the magnetic elongation would be increased. "We know nothing so far," Prof. Knott ob-

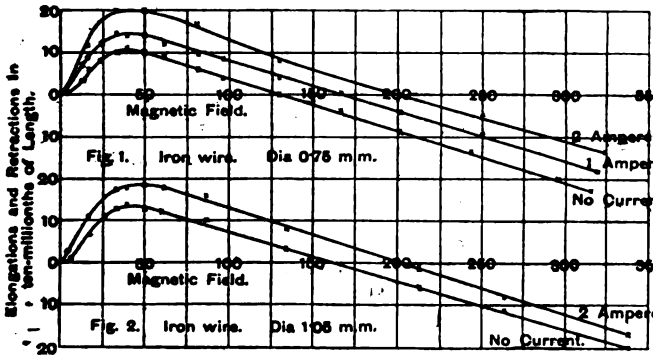
serves, "regarding the changes of length when an iron wire *carrying a current* is subjected to longitudinal magnetising forces;" and it was with the object of acquiring some information on this point and testing Prof. Knott's prediction that the experiments described in the present Paper were undertaken. The results show that it was amply verified, and thus Maxwell's explanation of the twist receives still further corroboration.

The apparatus used and the methods of observation were the same as those described in former papers. Each specimen of wire examined was 10cm. long between the supporting clamps, and the magnetising coil, weighing nearly 3lbs., was as usual supported by the wire itself, an arrangement which, for reasons before given, was essential. The indications of the instrument were read to one ten-millionth part of the length of the wire, and the wire was demagnetised by reversals before each single observation.

Exp. 1.—The wire first used was of soft commercial annealed iron, 0·75mm. in diameter. The changes of length which it exhibited under the influence of magnetising forces gradually increased from 13 to 315 C.-G.-S. units, are indicated (Fig. 1). The magnetising forces given are those due to the coil only, no account being taken of the demagnetising effect of the wire. It will be seen that the maximum increment of length, attained in a field of about 40, was 11·5 ten-millionths; the decrement of length in a field of 315 was 22·5, while the original length of the wire was unchanged in a field of 130.

Exp. 2.—A current of 1 ampere was then passed through the wire. In about two minutes the index came to rest, the number of scale divisions over which it had passed showing that the original length of the wire had increased by 310 ten-millionths. Assuming the coefficient of expansion of the iron to be 122 ten-millionths per degree Centigrade, this elongation denoted a rise of temperature (due to current heating) of about 2°·5. The experiment described in the last paragraph was then repeated, the several magnetising forces employed being made as nearly as possible the same as before by inserting the same resistances successively in the circuit.



The results appear in the middle curve of Fig. 1. The latter shows clearly that the maximum elongation had risen from 11·5 to 14·5 ten-millionths, while the decrement in a field of 315 had fallen from 22·5 to about 17·5.

Exp. 3.—The current through the iron wire was then increased to 2 amperes. The further elongation of the wire (due to the heating effect of the increased current) was very nearly 1,000 ten-millionths, corresponding to a rise of temperature of 8°·2 C. This, added to 2°·5, the rise due to the current of 1 ampere, which was passing before, give 10°·7 as the excess of the temperature of the wire carrying 2 amperes above that of the room. When the index had become steady, which happened in the course of about 2½ minutes, another series of observations was made. The results of the experiment are contained in the highest of the curves in fig. 1. There is again a marked increase of the maximum elongation, and decrease of the retraction in a field of 315.

Exp. 4.—The previous observations were repeated with another specimen of soft iron wire of greater diameter, viz.: 1·05 mm., no current being at first passed through it. The results appear in fig. 2.

Exp. 5.—A current of two amperes was passed through the same wire, resulting in an elongation due to heating of 460 ten-millionths, the temperature of the wire being therefore raised about 3°·3. The former observations were again made with the results given in fig. 2.

It will be seen that with both specimens of iron wire, the effect of a current is of just the same general character. It acts oppositely to tension, heightening the curve of elongation instead of lowering it. This action is certainly not due either directly or indirectly to mere current heating. It has been shown that the thinner wire, even when carrying two amperes, was only about 10°·7 warmer than when no current was passing through it. Such a small rise of temperature would be quite incompetent by itself to account for the effect in question, for the elongation curves of a given specimen of iron have been found to be not sensibly altered when taken under widely different conditions of temperature. Nor would it exert any material influence upon the susceptibility of the iron; and, even if it did, the curves would not be affected in the manner observed. It is hardly worth while attempting to frame an explanation until many more phenomena of the same order have been investigated.

Similar experiments were afterwards made with nickel and cobalt.

Summary.

In an iron wire carrying a current, the maximum magnetic elongation is greater, and the retraction in strong fields is less than when no current is passing. The effect of the current is opposite to that of tension.

The magnetic retractions of nickel and of cobalt are not sensibly affected by the passage of a current through the metals. (Tension considerably modifies the magnetic retraction of nickel, but not that of cobalt.)

PHYSICAL SOCIETY.

At an ordinary meeting of this Society on the 10th inst., Dr. GLADSTONE read a Paper by himself and Mr. W. HIBBERT on

"Some Points connected with the Electromotive Force of Secondary Batteries."

Last month we communicated a Paper to the Institute of Electrical Engineers, "On the Cause of the Changes of Electromotive Force in Secondary Batteries," which gave rise to a certain amount of discussion. Since then we have received a Paper by M. Darrieus, entitled "Essai de Théorie Chimique sur les Accumulateurs Electriques au Plomb;" which was read before the Société Internationale des Electriciens on May 4th. In it he agrees with Prof. Armstrong and Mr. Robertson in attributing the large initial electromotive force to persulphuric acid; and he opposes what he terms the most generally admitted theory of the production of sulphate during discharge, so far as the positive plate is concerned.

In our recent Paper we had assumed the truth of the view put forth by Messrs. Gladstone and Tribe in 1882, that in discharge "sulphate of lead is the ultimate product on both plates," and on discharging again "this lead sulphate is oxidated on the one plate and reduced on the other." This conclusion was not received at first without powerful opposition; but it has won its way to general acceptance among workers on the subject. Among these may be specially mentioned Prof. Frankland, Mr. Swinburne, M. Reynier, Messrs. Kohlrausch and Heine, Prof. Ayrton and his colleagues, and Mr. G. H. Robertson.

We can only attribute the finding by M. Darrieus of a large amount of oxide of lead mixed with sulphate on the positive plate to the fact of the difficulties of analysis, as it is hard to imagine that oxide of lead could remain as such when surrounded by sulphuric acid.

The reaction which takes place in discharging was expressed in our recent Paper by the general equation—

$$PbO_2 + H_2SO_4 \ldots H_2SO_4 + Pb = PbSO_4 + H_2O \ldots H_2O + PbSO_4,$$

and the reaction that takes place on charging was expressed by the same equation reversed. It is to be understood that these equations represent the initial and the ultimate products, and take no note of any intermediate reaction. There have been numerous theories in regard to such intermediate changes, but on these we must be held at present to express no opinion.

It is evident that if the reaction consists in the alternate formation and reduction of $PbSO_4$ there must be great changes in the strength of the sulphuric acid within the pores of each plate. How these changes must be affected, not only by the electrolytic reaction, but by the influence of gravitation and of diffusion, by electrical transference, by local action, &c., is traced out in our Paper. At the same time, continuing the experiments which were communicated to this society in 1890, we have not merely satisfied ourselves more fully that a change of strength of acid against the working surfaces of the plates results in a change of electromotive force, but we have determined the amount quantitatively for all strengths of acid from a mere trace to 99 per cent.

We show that the changes of electromotive force in charge and discharge coincide fairly well with the changes of strength of acid deduced *à priori*. For this purpose we employed the determinations lately published by Prof. Ayrton and his colleagues, believing them to be the best. Our conclusion is "that the changes of electromotive force in a secondary battery depend on the strength of the acid that is against the working surfaces of the plates."

The only serious opponents of our views, so far as we know, are Messrs. Armstrong and Robertson. They have attributed the changes of electromotive force to the persulphuric acid and hydro-

Digitized by Google

gen dioxide which are produced during the charge. The experimental grounds of this conclusion are not yet fully published ; but we are able to refer to their remarks in the discussion of our Paper, as printed in *The Electrician* of June 3, 1892. They commence by substituting for our general equation a complicated and unsymmetrical one, which at best can only be one form of it, and cannot represent those of our experiments that were made with the strongest sulphuric acid. Their subsequent remarks are addressed mainly to the supposed contamination of our sulphuric acid with the soluble peroxides, and to the probability of H_2SO_4 itself taking part in the reaction. Now, as to the first objection :—

Supposing that our plates in the first instance were not washed perfectly clean, there can be no reason why the trace of peroxide should always vary in amount with the strength of the fresh sulphuric acid in which the plates are dipped. As to the second objection, we have not speculated on hydrates of sulphuric acid in solutions, and have expressly stated that we "content ourselves at present with pointing out that the liquid in the secondary cell is a mixture, or a chemical compound, of two different liquids, sulphuric acid (H_2SO_4) and water, in varying proportions."

The most tangible criticism is directed not against our main experiments and argument, which are untouched, but against one of our confirmatory experiments. Messrs. Armstrong and Robertson say, "Two series of experiments were described by the authors, in which the electromotive force developed on the one hand between two lead plates and on the other between two peroxide plates in acids of different strengths, were measured. They appeared to regard these results as very important, as they went so far as to draw conclusions from a curve obtained by integrating the two sets of observations." They might have added that this curve coincides both in shape and magnitude with that previously determined when a Pb and PbO_2 plate were placed together in different strengths of acid. They attribute the results obtained with the two peroxide plates to the lead supports, because "local action would set in and be at a maximum in the stronger acid, and, therefore, the lead plate of this couple would be more protected, and the support opposite would be more active against the peroxide of this plate." The explanation is ingenious ; and we might welcome it, since it presupposes the truth of our own conclusion, that with a stronger sulphuric acid there is greater electrolytic action. It is, indeed, not impossible that the lead support may in some cases have a small influence on the result, but it is inconceivable that such large and uniform differences and such close coincidences as those shown in our Paper could be due to the accidental operations of local action. In this connexion they claim support from an experiment of ours with a plate dried at 100 per cent.; but a reference to Table 5 will show that in that experiment of ours we obtained not the highest, but really the lowest readings.

In order to show that the increase of electromotive force does not depend upon the presence or absence of persulphuric acid, we have within the last few days instituted the following two additional experiments. 1st. A Pb plate and a PbO_2 plate, perfectly free from dissolved oxides, were placed in pure sulphuric acid of 12 per cent. strength, a porous diaphragm being between the two. The electromotive force was 1·945. Into the acid surrounding the PbO_2 plate was placed one per cent of persulphate of potassium ; the electromotive force remained at 1·945. The lead plate was then brought into the same compartment, so that both were exposed to the influence of the persulphuric acid. The electromotive force was scarcely changed, viz., 1·934. 2nd. A secondary battery was made with phosphoric acid instead of sulphuric acid. Observations were made with different strengths of this phosphoric acid, varying in specific gravity from 1·05 to 1·5. The electromotive force increased with the strength of the acid ; and in the full range there was a difference of 0·196 volt. The theoretical variation calculated by Lord Kelvin's thermo-chemical law from the known heat of dilution would be about 0·170 volt. Of course there was no persulphuric acid, and we cannot assume the presence of any higher acid oxide of phosphorus corresponding to it, as such a compound is not known.

We have investigated the effect of charging and repose on the electromotive force of a small accumulator with phosphoric acid as the electrolyte, and found the results quite analogous to those obtained with sulphuric acid, as described in our Paper read at this Society in 1890, when we first announced our view that "the abnormal amount of electromotive force is due to the inequality of acid strength, and its gradual disappearance to equalisation of strength produced by diffusion."

Prof. AYRTON thought there was no question that the strength of acid had much to do with the changes of E.M.F. The point at issue, he considered, was whether the changes were direct effects of the strength of acid, or due to secondary actions brought about by alterations in strength.

Mr. E. W. SMITH said Mr. Robertson and himself were repeating the author's experiments with two PbO_2 plates without any grid. They had obtained results analogous to those mentioned in the Paper, but the true explanation of the effects was still to seek.

Mr. W. HIBBERT contended that the soluble oxides referred to by Prof. Armstrong and Mr. Robertson were not present in their experiments. They had also proved that changes in acid strength altered the E.M.F., whilst presence of persulphuric acid did not.

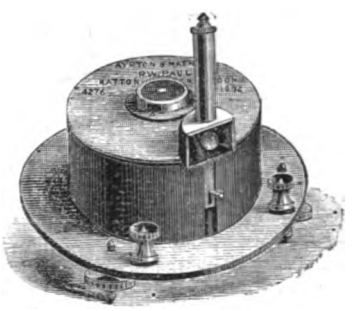
Dr. GLADSTONE, in reply, said they also were making experiments without grids, but had not made sufficient progress to discuss them at present. Mr. Hibbert and himself believed the effects of local action inconsiderable, whilst Messrs. Armstrong and Robertson thought them very important. He hoped that ere long the points would be settled conclusively.

Prof. AYRTON then read a Paper by himself and Mr. T. MATHER on

"Workshop Ballistic and other Shielded Galvanometers."

The galvanometers described were of the type having movable coils and fixed magnets, the advantages of which are well known. In designing the ballistic instruments their aim had been to obtain sensibility and portability, combined with being screened from external influences, for it was often desirable to measure the magnetic fluxes and fields in dynamos by apparatus near the machines. One of the improvements adopted was the narrow coil described in a Paper "On the Shape of Movable Coils," &c , read before the Society in 1890. Such coils are particularly advantageous for ballistic instruments, for not only can greater swings be obtained by the discharge of a given quantity of electricity through such a coil, than with ordinary shaped coils when the periodic times are the same, but even when the same control is used, the same length of wire in the coil, and suspended in the same field, the narrow coil is more sensitive to discharges than coils of any other shape. Another improvement was the use of phosphor bronze strip for the suspensions, instead of round wire. For a given tensile strength, both the control and the sub-permanent set could be diminished by using strip.

In February, 1888, the authors made a d'Arsonval of the ordinary type as a ballistic instrument, and found that although it was suitable for comparing condensers, yet for induction measurements the damping was excessive unless the resistance in the circuit was very large ; this greatly reduced the sensitiveness. In 1890 they tried one of Carpentier's milliampere meters as a ballistic instrument, but found it unsensitive. A narrow coil instrument made in the same year was found to be sensitive for currents ; but as the



coil was wound on copper to get damping, it was not suitable for ballistic work. In January, 1892, a somewhat similar instrument was constructed for ballistic purposes, and was found very sensitive and convenient. Although the coil had only a resistance of 13 ohms, one microcoulomb gave a swing of 170 divisions on a scale 2,000 divisions distant, the periodic time being 2·7 seconds. The instrument could be used near electro-magnets or dynamos, and was so sensitive that for ordinary induction measurements very large resistances can be put in series with it, thus reducing the damping to a very small amount. On the other hand, the coil could be brought to rest immediately by a short-circuit key. It had the further advantage that it was not necessary to redetermine its constant every time it was used. The chief disadvantage of such instruments was the variable damping on closed circuits of different resistances. This could, however, be overcome by arranging shunts and resistances so that the external resistance between the galvanometer terminals was the same for all sensibilities. A portable ballistic instrument intended for workshop use was next described. This had a narrow coil and a pointer moving over a dial, whose whole circumference was divided into 200 parts. The instrument had been designed to give a complete revolution for a reversal of a flux of two million C.-G.-S. lines, but the pointer could turn through two or more revolutions. To test stray fields a test coil with a total area of 10,000 square centimetres is used, and has a trigger arrangement for suddenly twisting it through two right angles. The instrument then reads off directly the strength of field in C.-G.-S. lines. To vary the sensitiveness in known proportions resistances are employed.

Referring to the improvements made in movable coil instruments since January, 1890, when a Paper on "Galvanometers" was read before the Society by Dr. Sumpner, and the present authors, Prof. Aryton said Mr. Crompton had greatly increased the sensitiveness of Carpentier's instruments by suspending the coils with phosphor bronze strip. Mr. Paul had brought out a narrow coil instrument (*see* figure) which combined the advantages of portability, deadbeatness,

Digitized by Google

quickness and sensibility. Specimens of these instruments were exhibited. The narrow coils are enclosed in silver tubes, which serve to damp the oscillations. Such a coil is suspended within a brass tube, which also forms the mirror chamber, and slides down between the poles of a circular magnet fixed to the base. To clamp the coil, a plug mounted on a slotted spring passes through a hole in the brass tube. A tube can be taken out and replaced by another containing a coil of different resistances in a few seconds. An instrument of this kind, with a coil of 300 ohms, gave 95 divisions per microampere, and the damping on open circuit such that any swing was ⅓ of the previous one. On comparing recent instruments with those mentioned in the Paper on "Galvanometers" above-referred to, a distinct improvement is apparent, for their sensitiveness is, for the same resistance and periodic time, as great as that of Thomson instruments.

Prof. PERRY remarked that the forces dealt with were extremely small.

Mr. SWINBURNE thought that ballistic galvanometers might be regarded as instruments indicating the time integral of E.M.F. rather than quantity. Illustrating his meaning by reference to dynamos, he said that if two machines arranged as dynamo and motor were joined by wires, then if the armature of the dynamo were turned through any angle, that of the motor would move through the same angle, supposing friction, &c., eliminated. Speaking of figures of merit he pointed out that the power consumed was the important factor.

Prof. S. P. THOMPSON inquired what was the longest period yet obtained with narrow coil instruments. The decay of magnetism in large dynamos was so slow that very long periods were required. He himself had used a weighted coil for such measurements. He also wished to know why the figures of merit were expressed in terms of scale divisions on a scale at 2,000 divisions distance, instead of in angular measure or in tangents. He thought that in testing magnetic fluxes by the workshop ballistic instrument the test coil might be left in circuit, instead of putting in another coil.

Mr. E. W. SMITH asked what was the length of strip required to prevent permanent set when the deflection exceeded a revolution.

Mr. A. P. TROTTER wished to know what error was introduced by the change of damping caused by the resistance of the circuit not being quite constant.

In his reply, Prof. AYRTON said Mr. Boys had pointed out that the scientific way to lengthen period was not by weighting the coils or needles but to weaken the control. Periods of 5 seconds had been obtained. At present it was not easy to obtain longer periods, owing to difficulties in obtaining sufficiently thin strip and to the magnetism of materials.

OVERHEAD WIRES.

LONDON COUNTY COUNCIL BY-LAWS.*

The Special Committee which was appointed at the recent annual meeting of the Electrical Trades Section of the London Chamber of Commerce to consider and take action in regard to the County Council by-laws, has drawn up a petition, of which the following is a copy, and which is being presented to the Board of Trade in the name of the Chamber:—

The petition of the Incorporated Chamber of Commerce of London humbly showeth:—

1. That your petitioners, on behalf of its Electrical Trade Section, are interested in the "by-laws made by the London County Council in pursuance of the London Overhead Wires Act of 1891," and objections to which are shortly to be heard, and the clauses finally settled by your department.

2. That having considered the by-laws which the London County Council are empowered to frame under the Act, your petitioners have arrived at the conclusion that many of the provisions are wholly impracticable, and would place such insurmountable difficulties in the way of the companies interested, as to prevent them carrying on their business, and are quite unnecessary for the public safety.

3. That your petitioners aver that the Companies fully realise that it is in their own interest and that of the electrical industry generally that proper safeguards should be provided for the safety of the public from accidents arising from carelessness in the erection or maintenance of overhead wires.

4. That your petitioners are prepared to co-operate, if need be, in the framing of any reasonable legislation for the proper control and regulation of overhead wires in the County of London, and would wish to indicate that they regard the by-laws framed and recently passed by your department for the regulation and control of overhead wires in the provinces as being generally reasonable, and such as will not stultify and hamper the development of the industry, while at the same time sufficiently safeguarding public interests.

5. That your petitioners object to Clauses 1, 2, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 15, 19, 20, and 21 of the regulations as now framed by the County Council, the reasons, where such are given, being here set opposite the numbers of the clauses referred to.

Interpretation of Words.—That the interpretation of "company" as including "person" may be taken to mean any person using a wire—*e.g.*, a subscriber to a telephone company.

Clause 1.—That the "plan" which is required is in excess of the powers granted to the London County Council under Clause 5 of the London Overhead Wires Act of 1891. That the regulation is an impracticable one. That to comply with it a special staff of clerks and inspectors would require to be continually employed in view of the constant changes which are being made in the routes of wires to suit the requirements of telephone subscribers. That the attendant expense would be very serious, and even if practicable, the time allowed (three months) is much too short.

Clause 2.—That the requirement of fourteen days' notice giving particulars of the wires proposed to be erected is far too long, inasmuch as wires have frequently to be erected and removed at a day's notice, *e.g.*, in the case of visits of royal personages, and also police requirements where only a few hours are allowed. That even in ordinary circumstances, it would be impossible to comply with the regulation, the route of the wire having to be so often changed in the course of construction. That the provincial by-laws recently settled by the Board of Trade under the Public Health Act provide only for a *route form* without drawings, being sent in one month *after erection*, and this it is contended would be sufficient in the case of London.

Clause 4.—That to require that all wires shall not be at a less height above the roof of any building than seven feet would, unless accompanied by compulsory wayleaves, make overhead wires almost impossible in some districts of London owing to the irregularity of the buildings. The enforcement of the clause would be a serious interference with the use of poles and standards. The height can add neither to the safety of the wire or its supports, nor, consequently, to the safety of the public. No such provision has been insisted upon in the provincial by-laws.

Clause 5.—That the London County Council should have power to permit an excess of 140 yards in special cases.

Clause 6.—That it is impossible to determine the angle in the case of many of the London streets, owing to their irregularity. That no similar regulation is contained in the provincial by-laws.

Clause 7.—That the words after "length of span" should be deleted so as to correspond with the provincial by-law.

Clause 8.—That no restriction should be placed on the Companies which would prevent the use of copper, as would be the case if this clause were insisted on. The enforcement of the clause would necessitate the removal of the present wires and the substitution of others, if indeed it is possible to find a wire by which the factor of safety required under the conditions could be guaranteed.

Clause 9.—That the word "pole" should be substituted for "support.'

Clause 10.—That the terms of the by-laws are in excess of the powers conferred on the London County Council under the Act. That no such enactment is provided for in the provincial by-laws.

Clause 11.—That this clause is a most unreasonable restriction, which, as has been proved by past experience, is quite unnecessary. That at least four times as many wires are carried on the present poles, and that to require that only 20 shall be erected where so many have hitherto been used with safety is to aim at the total and complete extinction of the entire overhead system, and consequently at the stoppage of all telephone exchange business in London.

Clause 12.—That cables are now in use weighing 6lb. per yard, and have not proved to be in any way dangerous, and further, that they have been erected for years weighing 2lb. per yard instead of 11lb., as mentioned in the clause, and that not a single case is known of a broken cable. That even if practicable the carrying out of the clause would prove to be so costly as to be absolutely prohibitive. Moreover, that experience proves it to be quite unnecessary, and that it is beyond the powers conferred by the Act.

Clause 14.—That to insist on the shoes of supporting poles being of iron is to resort to an old-fashioned system which might prevent the adoption of improved methods. That no such provision is contained in the provincial by-laws.

Clause 15.—That there is frequently great difficulty in efficiently connecting the wire to earth. That owners and tenants of property have grave objections to the erection of lightning conductors, and often refuse sanctioning the erection of any wires on such a condition. That a lightning conductor might prove to be a source of greater danger than protection to tenants of buildings. That such a provision is not contained in the provincial by-laws.

Clause 19.—That for this clause, No. 3 of the provincial by-laws should be substituted, which reads:—"Every wire or tube, after it has ceased to be used for the purpose for which it was stretched or placed, or for some similar or other proper purpose, must be removed, unless its owners intend within a reasonable time again to take it into use."

Clause 20.—That the Act does not provide for inspection, and that the clause is, therefore, *ultra vires*. That in any case it should be deleted, it being unreasonable to suppose that the companies can contract for the invasion at any time of business or domestic privacy.

Clause 21.—That the words "or any of the provisions of the London Overhead Wires Act, 1891," should be deleted, your petitioners being of opinion that the Local Authority has only power to impose penalties for the violation of its by-laws, and that a violation of the provisions of the Act can only be dealt with under common law procedure.

Your petitioners for the reasons given are of opinion that the London County Council by-laws, as at present framed, are utterly impracticable and so unworkable as to defeat the object they have in view, which object your petitioners are interested in promoting by all reasonable means. That the by-laws should, therefore, be amended by your department in accordance with the views here set forth, and which will, no doubt, be supported by the independent testimony and technical knowledge of the representatives of the companies interested, and that while efficient safeguards for the public safety ought to be provided, this it is contended, can be done without ruthlessly interfering with the ordinary business methods of not only a growing but an indispensable industry to the public convenience

See *The Electrician*, December 11, 1891, page 149.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—THURSDAY, JUNE 9TH.

Select Committee on the Electric Railway Schemes.

The Great Northern and City Bill came on Thursday last week before the Select Committee presided over by Sir John Kennaway. Mr. Cripps, Q.C., Mr. Moon, and Mr. Tyrrell appeared for the promoters. Petitions against the Bill were presented by the Commissioners of Sewers of the City of London (counsel reserved), the Corporation of London (counsel reserved), the North Metropolitan Tramways Company, for whom Mr. Pope, Q.C., Mr. Rickards, and Mr. Richardson appeared; the Metropolitan Railway Company, for whom Mr. Littler, Q.C., and Mr. Worsley Taylor, Q.C.; and the Gaslight and Coke Company, the London Hydraulic Power Company, and the Vestry of St. Mary, Islington, for whom there were no appearances.

Mr. CRIPPS, in opening the case for the promoters, said the proposal in the Bill was for a line running from Moorgate-street, in the City, to a junction with the up and down lines of the Great Northern Railway, near Finsbury Park Station. The first line would form a junction with the up line of the Great Northern main line, the second would form a junction with the down line, and the third, starting from Drayton Park, to the City, the three lines forming the connection between the City and the Great Northern system. Between the two termini there was a very important traffic, and three stations were proposed, one at Drayton Park, one at Essex-road, and one at Old-street, in addition to the terminal station at Moorgate-street. The purpose of the line was on the one hand to give relief to the suburban traffic of the Great Northern Railway, which had increased enormously, and, on the other hand, to accommodate a very important local or omnibus traffic between Drayton Park and Moorgate-street in the City. There was a main point of difference between this proposal and the Baker-street scheme, on account of the junction proposed. The diameter of their proposed tube was 16ft., and that would enable them to run trains from the Great Northern main line over their line into the City. It was felt that the traffic could not have been dealt with by any system of changing trains. There was no question of the practicability of a system of electricity for a line of this kind. Near Drayton Park there would be a depôt for the development of their electrical power, and from there to the City the trains would be run by electric power. The traffic from the North of London, from Enfield, East Barnet, High Barnet, and Edgware, all concentrated at Finsbury Park, and could be carried forward either by the Metropolitan line from King's Cross to Moorgate-street, or by the North London line to Broad-street; but in spite of this the traffic had assumed such congested proportions that some relief must be given. On the Great Northern 85 trains were run each way a day, 48 by the London, Chatham and Dover to Victoria, and 80 each way by the North London to Broad-street at the present time. The traffic over the Great Northern system had developed at the rate of nearly an additional million a year.

Sir DOUGLAS FOX, C.E., who was the first witness, stated that he was engineer for the line jointly with Mr. Greathead. Their first idea had been to lay out a line somewhat similar to the other lines which were before the Committee, and to run it up to Finsbury Park, and have an exchange station with the Great Northern Company there. They found, however, afterwards that the Great Northern Company made it a *sine quâ non* that they should be able to run their suburban trains straight through without a change of carriage. In this particular case it would have cost them as much to construct a smaller line up to Finsbury Park as it did now to make this larger line terminating at Drayton Park. They found that they could construct a line in a 16ft. tunnel capable of taking all the rolling stock of the Company as far as Drayton Park. There were large numbers of the working classes employed about Old-street and Essex-road who would be glad to avail themselves of the facility afforded by this line of getting farther out into the suburbs. The gradients and curves on the line were, he thought, very satisfactory for accommodating the main line traffic of the Great Northern. The steepest gradient was 1 in 45 on the first line, on the second there was a small piece of 1 in 53, and on the third 1 in 66. The estimated cost was £1,199,325, to which must be added £250,000 for the lifts, electric installation, and plant. It was proposed to put the installation close to the Drayton Park Station, at a point that was away from all houses, and where there would be no difficulty. The line would be about 2½ miles in tunnel and 3 miles altogether. Excluding Sundays and holidays, they estimated that the return would be 5s. per train mile, giving net earnings for the year of £62,360. A Great Northern engine would run from Finsbury Park to an electric engine from Drayton Park to the City.

Several residents from the north of London having given evidence with regard to the insufficient train service to the City at present existing,

Mr. ALEXANDER SIEMENS was called, and, in reply to Mr. Pope, said he was interested in the question of the increase of size of the ordinary electric locomotive which would be necessary on this line. The difficulty has been to convince people that they can invest their money safely in larger locomotives. I believe that electric traction can only be applied economically in cases where there are frequent trains for long hours. Therefore electric traction, *primâ facie*, is only applicable to suburban lines or tram lines where there can be a frequent service throughout the day. If there were not frequent trains it would be very costly to apply electrical power; but then there would be other considerations, such as ventilation, which make electrical power desirable, even if it was not as cheap as steam power. I certainly anticipate that the electrical power will prove to be cheaper than steam.

But at all events there is no instance in the world, is there, of the application of electricity as a motive power to a full-sized locomotive?—I am not quite certain about that, because the Thomson-Houston Company have the order to supply full-sized locomotives to take the ordinary traffic of the Baltimore and Ohio Railway from Baltimore.

That would be reducing to practical results what at present is rather scientific opinion?—Well, I do not know whether you can call it simply scientific opinion, because if you know the weight of the train and the speed, and the line over which you draw it, you know the power you want, and then you know also what weight your locomotive ought to have. Therefore, it is not an unknown quantity; we know, for instance, that the locomotive to draw an 80-ton train ought to weigh at least 40 or 50 tons, and that it ought to exert an average power of 160 H.P., or a maximum power of very nearly 700. There is no difficulty in constructing dynamo machines which exert that power, and, therefore, from an engineering point of view, there is no difficulty whatever in making these engines; the difficulty rather is to get the public to invest their money in them.

Mr. LITTLER: What is the length of that small experimental piece of line on the Baltimore and Ohio Railway?—I believe about four miles. It is a tunnel.

Is there any experience whatever which would guide us as to the cost of this undertaking?—The nearest approach is the City and South London.

And the City and South London is 75 per cent. working expenses?—Well, you cannot take them altogether as examples, because there are difficulties which you can avoid in a new line.

With regard to capital cost?—No, with regard to working expenses. I think they have an unusual amount of repairs to do.

Is there not any line which is on all fours with this line?—There is the experience of the central stations for electric lighting, which generate electricity just the same as the station at Drayton Park will have to do; because it is entirely the same whether the electricity is used for lighting or for power.

The lighting electricity is sent along wires, is it not, and this is to be used wo king along the railway, you are to have your cars drawn by it, and you are to use it not as a lighting agent but as a motive agent. Is there no experience of it as a motive agent except the City and South London?—Any amount.

On a railway?—No, not on a railway.

Mr. CRIPPS: I see that in giving evidence before the Joint Committee you spoke specially of this Great Northern and City line. Taking the necessary horse power here do you provide and guarantee the necessary locomotives?—Certainly.

The CHAIRMAN: You have no doubt in your own mind that it can be done?—None whatever.

Sir HENRY OAKLEY, General Manager of the Great Northern Railway, was then called. He said the Great Northern Company would welcome the new line as an additional means of relieving their congested traffic. There would be no difficulty he thought in changing the engines at Drayton Park Station. At the present time they could not send any greater traffic over their rails during the busy times of the day. The route went so directly to the heart of the city that he could not doubt that such a line would prosper independently of their own.

At the close of the promoters' case Mr. Littler applied for a Speaker's Order to ensure the attendance to-morrow of the four gentlemen nominated as Directors of the railway, Baron Camoys, Mr. D. Bayley, Mr. J. H. Borrer, and Mr. R. Richards, in order to show how they proposed to raise the capital, but the application was refused.

After hearing some further evidence the Committee adjourned.

FRIDAY, JUNE 10TH.

On Friday Sir John Kennaway's Select Committee again sat to consider the Great Northern and City Bill. It was intimated that the Committee would not deal with the remaining Bills this Session.

Mr. BELL, the manager of the Metropolitan Railway, was then recalled. He said that if the Great Northern Railway were to run their trains as regularly as they ought, it would make a great difference in the receipts of his line. His Directors had tried to make arrangements for electrical experiments to see if the railway could be worked in that way, and had offered very favourable terms to electricians, but without so far obtaining any result. Omnibuses and trams put on overhead along the route of the Metropolitan Railway had seriously affected the traffic on the line. When the Walham Green 'bus was put on from King's Cross, it affected their receipts to the extent of £200 per week. There was no comparison between the Metropolitan Railway and the one now proposed. The number of passengers who came to them from the Great Northern a year was 7,000,000, for whom they received £22,000. From the four companies who worked over their line they received £92,000 a year.

Sir E. WATKIN, Chairman of the Metropolitan Railway, was the next witness. He regarded the line as practically an extension of the Great Northern to the City. He did not think that the Great Northern ran a maximum number of trains over their line during the busy times of the day, because they ran at irregular intervals of 7, 9, and 10 minutes, and so on.

Mr. LITTLER urged that the Metropolitan Company would not have contracted to pay £14,000 a year for the two lines constructed between King's Cross and Moorgate-street if they thought their traffic would be afterwards taken away from them by a scheme such as the present one. The time he thought had not come for all these experiments. If they did not succeed they would be absolutely useless and would obstruct the advancement of other schemes. He suggested that a trial should be given to one of them, the Central London, for instance. The City and South London Railway had been a failure up to the present time.

Mr. W. E. HAMMOND, Traffic Superintendent of the North Metropolitan Tramways Company, was then called to give evidence in opposition to the Bill. Their mileage was 49, which returned £28,600 per mile. Last year they carried 15,270,000 passengers, their earnings being £430,000 gross and £94,812 net. The proposed line would very seriously compete with the business of his Company.

Digitized by Google

Mr. POPE then addressed the Committee on behalf of the North Metropolitan Tramways Company, and contended that it had not been ascertained that the creation of the power necessary to move the weight proposed could be sufficiently remunerative to justify such an expenditure. They were asked to introduce a competition to an existing statutory company created under special circumstances. He did not say any man was to blame for spending his money in advancing electrical science; but some people were, perhaps, unduly tempted sometimes in the interests of science to risk unwisely the little they had gained, and it was scarcely advisable to give any additional impulse to speculation of this sort.

Mr. CRIPPS, for the promoters, stated that if the Committee passed the preamble they would do all they could to meet the Tramways Company and their other opponents on points of difference.

The CHAIRMAN announced that the Committee considered the preamble passed. Clauses were then gone into, and the Bill was ordered to be reported to the House for third reading.

WEDNESDAY, JUNE 15TH.

Select Committee on the Telegraphs Bill.

The Select Committee of the House of Commons, to which the Telegraphs Bill now before the House has been referred, met on Wednesday; and, in the absence of the Chancellor of the Exchequer, the chair was taken by Sir James Fergusson. The other members of the Committee are, Mr. Crilly, Mr. W. Cross, Mr. John Ellis, Colonel E. Hill, Mr. Atherley Jones, Mr. Lafone, Mr. Leon, Mr. Summers, Mr. Taylor, Mr. Shaw Lefevre, and Sir Richard Temple.

Mr. J. C. LAMB, Assistant Secretary to the Post Office, who was the first witness, said that about 90 or 95 per cent. of the telephonic business of the country was now conducted by companies. The Post Office had exchanges with several important towns, however; they had a very considerable exchange with Newcastle-on-Tyne and the neighbouring towns, a flourishing exchange with Hull, one in which the colliery districts and the towns of South Wales were combined, one with Leicester, and with one or two other places. The necessity for the present Bill had been felt for some time, owing partly to questions which had been put in Parliament, deputations from different Chambers of Commerce and other bodies, and to articles and letters in the public press, but principally to the effect on the telegraph revenues of the extension of telephonic communication. Taking the gross receipts for certain weeks in the present year and comparing them with the corresponding weeks in last year, they found a falling off in the telegraph revenues which they could only attribute to this cause. A return had been made some time ago from which it appeared that in a given period the increase over the whole country in telegraphic business was 108 per cent.; whereas in the same period the rate of increase in some of the busy districts, where telephonic communications existed between the large towns, was much less; between Manchester and Liverpool it was only 72, between Glasgow and Leeds 67, Leeds and Bradford 79, Leeds and Huddersfield 73, Leeds and Dewsbury 51, and Glasgow and Greenock 30. He did not think that during that period there had been any very exceptional charge of a capital nature, but there had been a considerable increase in the charge for wages. By the scheme now before the Committee it was proposed to relinquish the charge for telegraphy to the telephone companies for wires connected with local post-offices, and to allow the companies to use the houses and shops of some postmasters as call offices, which it had been represented would be regarded as a boon by the companies. The head, district, and branch offices might also be used by the companies for special purposes, and these concessions were made in view of the Post Office taking over the main lines. It was thought that considerable assistance might be afforded to the companies if the Post Office itself undertook to lay down on rental terms the main lines required to connect their exchanges together in one and the same area. The companies did not at present possess any statutory rights in regard to over-house wires, but by virtue of certain legal decisions they enjoyed practically the right of laying wires over streets under certain conditions without the consent of the local authority. What was proposed was to confer by the Bill moderate statutory powers upon them for the erection of such wires, and to place them under obligation to obtain the consent of the local authorities. The Companies had complete metallic circuit trunk lines, and the Government attached so much importance to metallic circuits that it desired that the exchange system should be so conducted.

The CHAIRMAN: Are you satisfied with the weight of the metal on the trunk lines?

WITNESS: We have reason to believe that the weight of copper is not sufficient to allow of satisfactory conversations over long distances. They proposed to have main wires from London to Belfast and to Edinburgh, and there would be spurs to Newcastle and the neighbouring towns, to Hull, Manchester, Liverpool, Sheffield, Nottingham, Derby, Leicester, and other important centres. About £400,000 would be spent in additional lines, and £600,000, he thought, would enable them to purchase the trunk lines and fill up gaps here and there.

By Sir RICHARD TEMPLE: There was no telephonic communication at present between England and Ireland, but they proposed to establish one by submarine cable.

Mr. R. HUNTER, solicitor to the Post Office, who was the next witness called, said he had prepared some amendments to meet the views of municipal corporations.

Mr. J. S. FORBES, Chairman of the National Telephone Company, said that at the present time the telephone companies conducted a great deal of their business very badly, but this was the fault of Parliament in not allowing them the necessary powers. He thought the Government should either take over the companies altogether or co-operate with them in carrying on the telephonic service. The best means of doing that would be to give the companies further powers.

The Committee then adjourned.

THURSDAY, JUNE 16TH.

After hearing further evidence (which will be given in our next issue) the Committee decided to pass the Bill substantially as it stood, and agreed to the following special report:—

REPORT.

The Bill referred to your Committee is for the purpose mainly of enabling the Treasury to raise the sum of £1,000,000 for the purchase of the trunk lines of the Telephone Companies if an arrangement contemplated between the Post Office and the Telephone Companies can be carried out; and for the erection of other trunk lines. The terms of the agreement have been laid down in a Treasury Minute presented to your House. No final arrangement, however, has been arrived at between the Post Office and the Companies. The Telephone Companies have appeared before the Committee and have urged that upon many points the terms of the arrangement should be modified in their interests. The greater number of these points are matters of detail, which, though of considerable importance, may properly form the subject of negotiation between the Companies and the Department, but on which your Committee offer no opinion. There is, however, one point of public policy of considerable importance, namely, whether the licences of the Telephone Companies originally granted for 31 years, of which about 19 are unexpired, should be extended. The Companies ask for considerable extension of their present terms. Your Committee do not recommend that the terms of these licences should be extended. With this reservation the Committee are of opinion that the responsibility for the details of an agreement with the Companies must rest with the Government, but they think that the agreement should be laid before Parliament.

WESTERN COUNTIES AND SOUTH WALES TELEPHONE COMPANY (LIMITED).

A full report of this Company's meeting on Wednesday last appeared in our issue of the 10th instant, from which it could be seen that the National Telephone Company are taking over the Western Counties and South Wales Telephone Company, and amalgamating it with their general provincial system. A memorial was sent to the Western Counties Company by the members of the Bristol Stock Exchange, suggesting another arrangement; and the following letter in reply has been addressed to the Bristol Stock Exchange by the Directors of the Western Counties Company:—

"GENTLEMEN: I am instructed by my Directors to inform you that they have carefully considered the memorial or letter addressed to them by the members of the Bristol Stock Exchange; and although the Directors think it probable that they know more of the affairs of the Company than can be known to any other association, they are nevertheless prepared to discuss all points brought under their notice.

"If the signatories of your memorial will give a firm offer to raise a sum of, say, £100,000, upon Second Preference Shares at such a rate of interest as will not exceed the earning power of this Company, my Directors will submit the proposal to the National Company, and suggest that they give to the Western Company an option of either accepting the terms of amalgamation, now under consideration, or of raising additional capital for the continuation of this Company as a separate undertaking. But, in the opinion of my Directors, it would be useless to propose the raising of capital without at the same time showing that it can be effected upon reasonable terms.—Yours truly,

(Signed) "H. F. LEWIS,
"General Manager and Secretary."

The following figures issued by the Western Counties and South Wales Telephone Company show the general business of the Company for the past seven years, and supplement the figures given in the Directors' report which appeared in our last issue:—

TELEPHONIC COMMUNICATIONS OR MESSAGES.

Year.	Trunk.	Local.	Total.	Gross Revenue.
	£	£	£	£
1885	—	1,193,334	1,193,334	8,750*
1886	—	1,942,044	1,942,044	9,914
1887	54,676	2,811,426	2,866,102	15,569

CORRESPONDENCE.

ELECTRIC LOCOMOTIVES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of June 3rd you were good enough to publish a correction of a passage in the new edition of my "Dynamo-Electric Machinery." I desire to supplement this by saying that the statement that the electric locomotives supplied by Messrs. Mather and Platt (Limited) for working the City and South London Railway "are now being replaced" by others is not only technically inaccurate, but altogether incorrect, and to express my regret that inconvenience and annoyance should have been caused to Messrs. Mather and Platt by such a statement. I now learn from Messrs. Mather and Platt that the rolling stock of the electric railway is about to be increased by the addition of another locomotive which is being constructed by them.—Yours, &c.,

June 14, 1892. SILVANUS P. THOMPSON.

PROF. DEWAR'S LIQUID OXYGEN EXPERIMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The profoundly interesting experiments made by Prof. Dewar at his lecture last Friday at the Royal Institution have led me to think that a distinction should be drawn between the physical and chemical aspect of the change produced by the intense cooling of oxygen upon its store of energy. Prof. Dewar, dealing more particularly with the former phase, pointed out that as the velocity of the molecules of oxygen at $-200°$C. was only one-half that which they possessed at the ordinary temperature, they had of course lost three quarters of their *vis viva*; but he also touched upon the fact that their chemical affinity was greatly reduced. It is plain that to restore their former physical condition energy must be imparted to them from without; but it is not so clear that their chemical energy is really decreased—it may be only latent and incapable of exercise. In the contrary case part of the energy necessary to raise the temperature of the oxygen, that is to say, to increase the velocity of its molecules, would be used up in replacing their lost chemical energy; whence it follows that a correction, the amount of which is at present unknown, would be requisite to obtain the true value of the quantity of energy necessary merely to raise the temperature of oxygen from $-200°$C. to the ordinary temperature. Until the necessity of such correction is disproved, or its amount ascertained, the true specific heat of oxygen between these temperatures cannot be determined. The idea is capable of extension to all temperatures, in passing between which the chemical energy of a substance appears to alter. No doubt, Professor Dewar can give an authoritative explanation of what appears to be a point of some obscurity.—Yours, &c., B. B.

Westminster, June 14th, 1892.

NEWCASTLE CENTRAL-STATION COSTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent Mr. Yeaman will find all the information he asks for in our Paper *as read*, and in our reply to the discussion, which we will make as complete as possible.

You are quite right, Mr. Editor, in taking our divisor as a 30-watt lamp.

The last sentence of the last paragraph of the Paper read:—"The total cost of the unit sold (for this year to the date of the Paper) equals 2·51d., which includes all charges."—Yours, &c.,

NEWCASTLE UPON-TYNE ELECTRIC SUPPLY COMPANY (LIMITED),
R. C. JACKSON, Manager.

Pandon Dene, Newcastle upon-Tyne, June 13, 1892.

RUNNING ALTERNATORS IN PARALLEL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I see in your issue of the 10th inst. a letter from Mr. Charles H. Yeaman respecting the Paper read by Mr. Jackson at the Society of Electrical Engineers on the Newcastle Central Station. In the latter part of his letter he mentions the question of running alternators in parallel. If Mr. Yeaman would kindly read the article recently published in the contemporary to which he is an occasional correspondent, he will find that Deptford is not the only and by no means the most successful case of running alternators in parallel.

It has been done nightly in a most satisfactory manner, and with no hitch whatever, for over twelve months at West Brompton, which is, I believe, the only central station in England where alternators have been running in parallel for a continued period in actual work on the outside circuits.—Yours, &c., ALBERT GAY.

June 11, 1892.

WATER-POWER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your article in last week's *Electrician* on the above subject I observe you state that "by careful experiment the water (in cubic feet per minute) flowing over each foot of the notch has been found equal to $5·15\sqrt{h^3}$, where h = height of water over notch in inches," giving an accompanying table worked out on this basis. This, however, is only true when the notch in the board is the full width of the stream—a condition not usual in practice. When the notch is half the width of the stream the formula should be $4·8\sqrt{h^3}$, and when it is a quarter the formula is $4·59\sqrt{h^3}$, a reduction of about 7 and 11 per cent. respectively. The formula I have used is $7·72\ K\sqrt{h^3}$, where K has following values:—

Ratio of width of notch to width of stream	1	·9	·8	·7	—
K	·667	·66	·65	·61	—
Ratio do. do.	·6	·5	·4	·3	·2
K	·63	·62	·61	·6	·595

Unless the above deductions be made disappointment as to results may occur. I note also, by the way, that 66 per cent. is given as the greatest efficiency of water-wheels; I have read of overshot water-wheels giving as much as 75 per cent.—Yours, &c., W. GEIPEL.

Blackheath, June 12, 1892.

TRAIN LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to your leading article on train lighting in *The Electrician* of May 27th, I should like to make, with your kind permission, some remarks concerning the accidents arising from the use of compressed gas. First allow me to call your attention to the accident which happened three years ago in Vansee (1888) near Berlin, where the passengers were burnt and badly wounded. The train was standing still in a station, when one of the carriages caught fire through the explosion of a compressed-gas reservoir. The train was full of people, and most of them were burnt before the eyes of the *employés* at the station. Five weeks ago there also happened here in Budapest an accident on the Hungarian Royal Railway, caused by the explosion of a gas reservoir, and many people were injured. Last year accidents also occurred in France.

I still hold, therefore, that the use of compressed gas is very dangerous, and it also diffuses a pungent odour, and in stormy weather the light flares.—Yours, &c., G

Budapest, June 12, 1892.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The Technical Instruction Committee of the Plymouth Borough Council invite tenders for the supply and fixing of electric bells at the new Science, Art and Technical Schools, Tavistock-road, Plymouth. Specifications may be seen at the office of the Organising Secretary, at the Schools, where tenders must be delivered before 5 p.m. on Monday next, the 20th inst.

Digitized by Google

TENDERS ACCEPTED.—Messrs. Mather and Platt's London office has secured the contract for lighting the Huddersfield Town Hall. The work consists of fitting up the building complete with 271 16-c.p., 16 32-c.p., 319 50-c.p. and 14 100-c.p. lamps, the current for which will be obtained from the new central station now being erected.

——— We learn by cable that the tender of the International Okonite Company (Limited) for wires and cables for the lighting of Melbourne has been accepted.

———The successful tenderers for the electric lighting work at Dundee (see last week's *Electrician*, p. 552) were Messrs. Willans and Robinson (Limited); the Electrical Power Storage Company (Limited); Callender's Bitumen, Telegraph and Waterproof Company (Limited); the India Rubber, Gutta Percha and Telegraph Works Company (Limited); Messrs. Siemens, Brothers and Co. (Limited); and Messrs. J. and H. Whyte and Cooper. Tenders were received from 42 firms, four of whom tendered for the entire work.

RESULT OF TENDERS.—The following tenders were received for the wiring of the Civic Buildings in Dublin. The work was divided into four sections, and contractors were asked to tender for each section separately, and for the whole :—

J. G. Statter and Co.	£1,220	0	0
Edmundsons (Limited)	1,298	15	0
Fowler, Lancaster, and Co. (Limited)	1,500	0	0
T. Scott Anderson	1,554	0	0
Laing, Wharton, and Down	1,644	0	0
Rashleigh Phipps and Dawson	1,649	0	0
Croggon and Co.	1,650	0	0
John Pearce	1,838	8	0
J. K. Fahie and Son	2,000	0	0
Electrical Engineering Company of Ireland	2,458	10	5
Berry, Harrison, and Co.	2,504	10	0

The tender of Messrs. Edmundsons (Limited) for £1,298 15s. was accepted.

MINING AND GENERAL ELECTRIC LAMP COMPANY (LIMITED).—We are asked to state, in reference to a paragraph which appeared in our issue of the 10th inst., that although this Company is in liquidation, it is only with a view to reconstruction, which is now in course of completion. In the meantime, the business is continued as heretofore.

NEW BRANCH OFFICE.—Messrs. Woodhouse and Rawson United (Limited) have recently opened a branch office, show-room, and stores at 16, Fleet-street, Dublin, their former agencies at Belfast and Cork being given up. The whole of their Irish business is concentrated in Dublin, under the management of Mr. Arthur H. M. Francis.

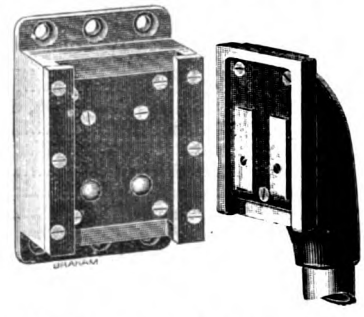
MESSRS. MORGAN WILLIAMS AND KING.—Mr. Morgan Williams, of this firm, has been instructed to act as consulting engineer to the Chiswick Local Board in carrying out their Electric Lighting Provisional Order.

MESSRS. J. B. SAUNDERS AND CO.—This firm have recently received instructions from Mr. J. H. Insoll to instal a complete electric lighting plant for Ely Court, Llandaff; a motor will also be used for pumping. The same firm have recently secured the contract for a complete installation at Velindra House, Llandaff, for Mr. P. A. V. Robinson. In the first installation a gas-engine will be used, and in the second a 7 B.H.P. Priestman oil engine.

DYNAMO BRUSHES.—Mr. James Dickson, of 48, Gray's Inn-road, London, W.C., has recently introduced the "Tieciton" Dynamo Brush, formed with strands of twisted wire plaited and cased with fine gauze. It is claimed for the new brush that there is no sparking,

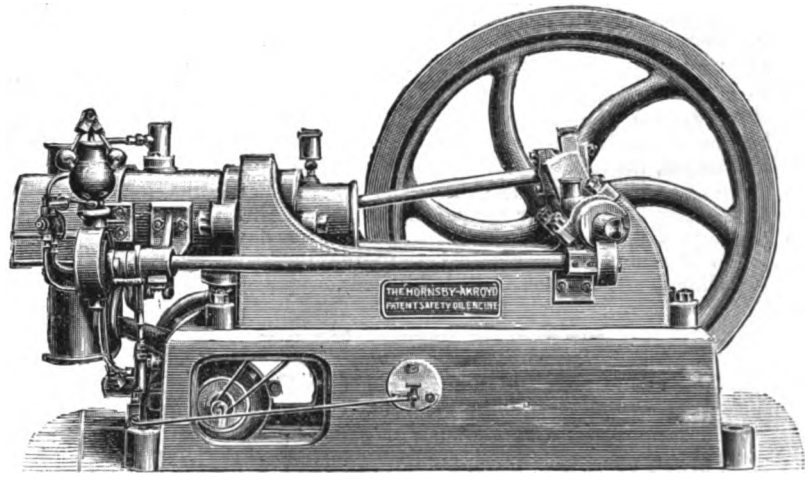
and no scoring of the commutator. The illustration above is a representation of the gauze casing lifted to show the plaited core. These brushes are already in use at a number of electricity supply companies' stations, as well as by several large engineering firms in London.

SHOP WINDOW ELECTRIC LIGHTING.—A new form of lantern for this purpose has just been put in the market by Messrs. Smeeton and Page, of 63, Queen Victoria-street, E.C. From the illustrations it will be seen that it is somewhat similar in appearance to the ordinary gas lantern, and is composed of silvered corrugated glass, instead of silver-plated copper used in gas lanterns. The corrugations in the glass add greatly to the brilliancy of the light, whereby a window may be lighted with about one-third the consumption of current of the old method by enamelled iron shades and high candle-power lamps. The reflector does not tarnish, and only requires wiping with a damp leather. The connection to the shop fascia is made by means of a detachable contact as shown below, and can be easily removed in the same manner as an ordinary gas lantern. When the lantern is removed, the front contacts fixed to the fascia may be short-circuited, without having any effect on the fuse, even if the controlling switch is on, as no current can pass until the lantern is in position, which also renders surface leakage impossible. Both the lantern and contact are very neat and effective, and are made in various sizes, and can be adapted to any window. They have been erected at the new premises of Messrs. Loewenstark and Sons, of 110 and 111, Strand, W.C., where they have proved a complete success.



ELECTRIC LAUNCHES.—The "Myionu," built by Messrs. Woodhouse and Rawson United (Limited), has recently had a new Woodhouse and Rawson motor placed in her, which enables her to run at a higher speed than formerly; and it is claimed that she is now nearly the fastest launch on the river. She has also been supplied with Epstein accumulators, which are charged at the rate of 50 amperes, enabling the charging to be done in three hours instead of six, as formerly. A new motor has also been added to the "Pioneer" by the same firm, and the steering gear has been carried forward to enable a cabin to be placed over her.

HORNSBY-AKROYD PATENT SAFETY OIL ENGINE.—We illustrate below the Hornsby-Akroyd Patent Safety Oil Engine, built by Messrs. R. Hornsby and Sons (Limited). They claim that the engine has now passed the experimental stage, and that, beyond a few minutes' heating up with a lamp before starting, no other means is



required to cause the explosions when the engine is running. Oil is used of a specific gravity of ·85, and the cost of working is claimed to be extremely small, equal to ½d. per indicated horse-power. Several of the engines will be exhibited at the Royal Agricultural Show at Warwick, including 4½, 8½, and 12 H.P. engines driving dynamos for electric lighting.

MESSRS. NEW AND MAYNE.—We are requested to state that this firm have started works at Woking for manufacturing electrical apparatus and patented specialities. These gentlemen were until lately managers to Messrs. Gill and Co. In addition to the works at Woking they have offices at Palace-chambers, Westminster, S.W.

Digitized by Google

PIER LIGHTING.—On Thursday, June 2nd, the new Royal pier at Southampton was opened by H.R.H. the Duke of Connaught. The pier is lit throughout by the electric light, the current for which is supplied from the local supply company's station. The work has been carried out by Mr. F. Shalders, contractor, Southampton, assisted by Mr. T. Davis, under the supervision of Mr. J. G. W. Aldridge, acting as engineer to the Harbour Board.

MESSRS. MATHER AND PLATT (LIMITED).—This firm have just issued neatly-printed illustrated particulars of their latest type of alternate-current dynamos. The illustrations show a No. 2 size with a direct-driven exciter and a No. 5 size for 1,000 volts, 120 amperes, at 400 revolutions. Tables accompany the list, giving particulars and prices of machines.

THE IMPERIAL INSTITUTE.—This Institute has recently been supplied by Messrs. Archibald Smith and Stevens with 11 hydraulic lifts, pumping engines and power storage plant; the system adopted being similar to that on which the lifts for the Electric Railway are worked.

MR. JOSEPH SLATER LEWIS.—The following is the list of this gentleman's creditors:—

Allen, A., Birmingham	£10	0	3
Andrews, J., Birmingham	12	0	0
Archdale (J.) and Co., Birmingham	295	7	0
Bailey and Co., Stroud	17	3	9
Barker (T. B.) and Co., Birmingham	82	11	8
Barrows, Birmingham	15	15	1
Buck and Hickman, London	103	6	10
Callender's Bitumen, Telegraph, and Waterproof Co. (Limited), London	17	2	7
Churchill and Co. (Limited), Birmingham	31	16	0
Davies, T., Frodsham	11	11	9
General Electric Company (Limited), London	15	8	10
Greening, C., Bradford	17	16	0
Hackett (J.) and Co., Birmingham	11	13	9
Haigh (W. B.) and Co., Oldham	27	10	0

Whiteley, W., Birmingham	13	4	6
Winter, F., London	10	13	10
and creditors under £10.			
LIABILITIES	£1,613	18	7
Fully secured creditors	1,683	15	9
ASSETS	nil.		

The bankrupt's examination will take place at the County Court, Birmingham, on the 29th inst.

BANKRUPTS' DISCHARGE.—Messrs. Allchin and Linnell, formerly trading at Northampton as electrical and general engineers, will be discharged, the former on August 5, and the latter on July 27.

JOURNALISTS ON THE THAMES.—The reporters of both Houses of Parliament held their annual dinner at Kingston on Saturday last, a pleasant feature of the outing being a trip down the Thames in an electric launch, kindly lent to the Pressmen by Messrs. Woodhouse and Rawson United (Limited).

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

May 14, 1892.

9,147. P. G. EBBUTT and J. B. VERITY. Birmingham. Improvements in or connected with electric fittings, such as fuse blocks, ceiling roses, switches, and the like.

9,148. P. G. EBBUTT and J. B. VERITY. Birmingham. Improvements in swing joints or ceiling connections, for carrying suspended electric light fittings, or combined electric light and gas fittings.

9,185. A. SHIELS. Glasgow. Improvements in couplings for electric wires.

9,192. A. J. BOULT. London. Improvements in the electrolysis of chloride and other solutions. (F. C. Bromley, France).

9,197. A. J. BOULT. London. A process of extracting zinc, iron, lead and copper from the solutions of their salts by electrolysis. (E. Liebert, Belgium).

May 16, 1892.

9,253. H. H. HALL. Liscard. Improvements in apparatus for indicating electrically words, numbers, places, or other terms.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "The Electrician" Electrical Trades Directory and Handbook, 1892, pages 308-322, *&c., &c.*]

ELECTRIC CLOCK COMPANY (LIMITED).—This Company was registered on June 9th with a capital of £1,200, divided into 1,170 ordinary and 30 founders' shares of £1 each. The objects are to carry on, conduct, create, subsidise, or otherwise assist or participate in commercial, public, financial, engineering, mining, and industrial undertakings, works, contracts, manufactories, and businesses; to carry on any business which may be considered advisable or conducive to the interests of the Company; and in particular, to enter into and carry into effect, with or without modification, an agreement to be made between Leon Pope, of 98, Richmond-road, Barnsbury, London, N., electrician, of the one part and the Company of the other part.

CHAMBERLAIN AND HOOKHAM (LIMITED).—The annual return of this Company, made up to April 26th, was filed on May 11th. The Company was registered on April 14, 1883, with a capital of £100,000, divided into 5,000 "A" and 5,000 "B" shares of £10 each. At the time of making up 1,000 "A" and 5,000 "B" shares had been taken up, of which the "B" shares had been issued as fully paid. Upon the "A" shares a call of £3. 10s. per share had been made, resulting in the payment of £3,500.

MARSHALL, SONS, AND CO. (LIMITED).—The annual return of this Company, made up to May 13th, was filed on the 19th. The Company was registered on August 21, 1862, with a capital of £20,000, in £20 shares. After several increases had been made in the capital, the capital was raised in March, 1891, to £400,000, in £20 shares; and, by a notice filed July 23, 1891, the shares, Nos. 1 to 10,000 inclusive, were converted into £200,000 stock. At the time of making-up, 2,000 shares, in addition to the £200,000 stock, had been taken up, and a call of £1 per share made, resulting in the payment of £2,000.

RANSOMES, SIMS AND JEFFERIES (LIMITED).—The annual return of this Company, made up to April 28th, was filed on May 3rd. The Company was originally constituted by Articles of Association dated May 1, 1884, and was registered on May 12, 1884, as a limited company, with a capital of £500,000, in £100 shares. At the time of making up, 3,075 shares had been taken up. Upon 2,185 of these the full amount had been called, while upon the remaining 890 shares £50 per share had been called, resulting in the payment of £263,000

SOUTHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, made up to June 6th, was filed on the 11th. Out of a nominal capital of £30,000, divided into 4,000 preference and 2,000 ordinary shares of £5 each, 10 preference and 688 ordinary shares have been taken up. Upon these the full amount has been called, resulting in the payment of £3,364, and leaving £126 in arrears.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 31st, was filed on June 8th. The Company was registered on January 9, 1877, with a capital of £2,445,630, in £10 shares. The capital is £2,445,630, divided into 200,000 ordinary, 34,563 first preference, and 10,000 second preference shares, of £10 each. At the time of making up, 83,321 ordinary, 34,563 first preference, and 4,669 second preference shares had been taken up, the full amount called, and all calls (£1,275,530) paid.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended June 12th were £745, as against £860 for the corresponding period of last year, being a decrease of £115. The total receipts to date, from January 1st last, amount to £18,936, against £17,780 in the corresponding period of 1891, being an increase of £1,156.

DIVIDENDS DUE.—*June 24*: Brazilian Submarine Telegraph Company (Limited), Interim, 3s. per share for quarter ended 31st March, nett. Books closed 17th to 23rd June.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—The Stock Exchange Committee have ordered £98,400 additional Four per

Digitized by Google

Cent. Mortgage Debentures of this Company to be quoted in the Official List. This Company notify that the Coupons due July 1st next on their Five per Cent. Mortgage Debentures, will be paid on and after that date at the banking house of Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—Application has been made to the Stock Exchange Committee to allow £104,900 Six per Cent. First Mortgage Debentures to be quoted in the Official List.

GREENWOOD AND BATLEY (LIMITED).—At the fourth ordinary general meeting, held on Friday under the presidency of Mr. Arthur Greenwood, the Chairman regretted that the Directors could not recommend the payment of a dividend to the ordinary shareholders; although he thought that, looking at the state of trade generally, it was matter for congratulation that the Company was not in a worse position. The report, which recommended a dividend of 7 per cent. on the preference shares, was carried.

SOCIETA GENERALE ITALIANA DI ELETTRICITA (SISTEMA EDISON).—Last year's working resulted in a profit of £7,934, and a dividend of 6½ per cent. has been declared.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended June 10, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,622.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 736.—Vol. XXIX. FRIDAY, JUNE 24, 1892. PRICE FOURPENCE. *Annual Subscription (U. K.), 19*

NOTES.

The letter which we print in this issue from Dr. E. Hopkinson gives some interesting information about the electrical working of the City and South London Railway; and the important statement that the weight of the carriages was increased from 4½ tons to 7 tons fully explains the over-straining, delays, and wear and tear which have been experienced. The fact that the working expenses per train mile turned out to be 25 per cent. less than the amount guaranteed, although the weight of the trains had been increased 40 per cent., speaks very highly both for the design and the management. The comparison of the yearly mileage of the Metropolitan District locomotives with those which have been built under Dr. Hopkinson's supervision is another interesting point, which, together with the fact that the mileage for the half-year on the City and South London Railway was only 188,666 against a proposed mileage of 384,000, shows what a great success may be expected from a line in which all these matters have been carefully considered and arranged, not only with careful calculation, but with the experience of actual working.

Dr. J. Hopkinson's transformer tests, a report of which we publish in this issue, are worthy of close study, as the method adopted, although lengthy, and somewhat laborious to carry out, is one which is susceptible of great accuracy. The main idea of the method is to directly measure the losses occurring in the transformer under different loads, and to deduce the efficiency by comparing these losses with the energy transformed. In this respect there is a close similarity to Dr. Hopkinson's well-known method of finding the efficiency of a dynamo from tests on a combination of dynamo and motor. The calorimeter method of measuring transformer efficiencies has the same characteristics, but the great difficulty of getting accurate results from heat measurements practically neutralises the advantages which this method would otherwise possess. The measurements required in Dr. Hopkinson's method are of a much more certain character, and the contact apparatus needed for the tests has been so often used for alternate-current researches that it should be regarded as a necessary part of the equipment of a good electrical laboratory.

The particulars of the tests have only just come to hand, so that it is impossible to adequately criticise the results. The efficiencies of 97 per cent. at full load and of 85 per cent. at one quarter load are very satisfactory. The numbers given show that the all-day efficiency of the transformer is as much as 92 per cent., assuming that the converter is worked for six hours at full load, and for 18 hours on open circuit. This high result will probably surprise the advocates of low potential systems of distribution. With regard to the losses occurring in the transformer, it seems remarkable that the eddy current losses should be so high. According to the tests the waste in hysteresis is one per cent., and that in eddy currents is 0·75 per cent. of the full load. The ratio of the latter to the former seems unnecessarily large.

The only reply that we can offer to the inquiry of Mr. Ferranti, which will be found in our correspondence columns, is, that the "committee of experts" of the Crystal Palace Exhibition is little else than a farce, and we believe that this is admitted by the majority of the members. The testing of the meters would have been one of the most simple jobs; and the only excuse for the committee and for the jury is that their nomination was thrust upon them by the promoters of the Exhibition, probably with the view of getting the use of their names. The Exhibition has been a splendid success without any assistance from these gentlemen, who have so generously consented to do nothing.

The internal or lost volts of a dynamo do not, as a rule, concern electrical engineers. They are taken, together with the demagnetising turns of the armature, as something to be overcome by the series-winding in a compound dynamo, and they enter into the calculations where dynamos are designed by calculation. These volts, together with the difference of potential between the terminals, make up the whole electromotive force of the dynamo, but they do not form part of the difference of potential. In an endless ring of a hundred cells, each having an electromotive force, or a difference of potential of one volt, it is impossible to find at any two points a difference of potential of one hundred volts; but an electromotive force of one hundred volts is present. In our description of the electric lighting at Oxford in another column we allude to the slowing down of a dynamotor before cutting out, to reduce the current to nothing. Supposing a constant pressure of one hundred volts is maintained on a circuit, and three dynamos in parallel are delivering, say, one hundred amperes each into the circuit; the difference of potential at the terminals of the dynamos is one hundred volts. If one of them be slowed down so as to

Digitized by Google

contribute no current to the circuit, it cannot be said to run at a lower voltage, for the volts at the terminals are still one hundred; the same as before. The difference of potential has not changed, but the electromotive force has been altered. The difference consists in what may roughly be called the fall of volts over the armature, though no such fall can be measured by any voltmeter or electrometer. As a matter of fact, it is very difficult to make several dynamos share a load evenly, especially if driven by separate engines, since this difference is so small.

The problem of the connection between ether and matter is one which excites a great interest among theorists, but its solution seems at present beyond the reach of experiment. In this respect it resembles the problem of determining the seat of electromotive force in a voltaic cell, or of determining whether the lines of force rotate with a magnet when revolving about its axis. In each case it seems difficult to devise any crucial experiment to decide between two rival theories. It will be seen that most of the experiments referred to in Dr. Lodge's able summary, which he recently gave to the Physical Society, and which we print in abstract in another column, yielded only negative results, so that any conclusion drawn from them is doubtful.

The whole subject is very abstruse, yet it is closely concerned with much that is of interest to practical electricians. For instance, in the case of an armature revolving between the field-magnets of a dynamo, everyone has a clear idea of the mechanical force exerted on the conductors which convey the currents. We have also definite notions of the currents induced in the conductors by their motion across lines of force. The mechanical power used to turn the armature is transformed to the electrical power possessed by the currents. Of the process of transference we, however, are quite ignorant. From one point of view we look upon the armature conductors merely as a material substance pulled round by mechanical force; but from the other standpoint we regard the wires merely as paths, and have no occasion to think of the matter of which these conductors are composed. The mechanical force exerted depends on the current through the wire; but this force is exerted, not on the electric current, but on the wire itself. In the connection between ether and matter, when discovered, will perhaps be found the solution of the great problem of gravitation. The law of attraction according to the inverse square of the distance is already explained for electrical and magnetic phenomena by the action of contiguous particles of ether; and it seems most probable that the solution of these other difficult problems will ultimately be found in researches of an electrical nature.

At a meeting of the Common Council at the Guildhall on the 16th inst., a report was presented on the position of the Corporation as regards the City and Guilds of London Institute, and it was recommended that no further contribution should be made for a year or two. The refusal of the Corporation of the City of London to support the City and Guilds of London Institute will surprise many of those who are unacquainted with the details of the management of this foundation. The fees of the students are manifestly inadequate to meet the expenses, and it seems that it was never intended from the first that either of the branches should be self-supporting. The City of London has contributed less even than one of the Guilds, viz., the Drapers', and has lately been taking less and less interest in the Institute, which, therefore, seems to stand in need of a new title.

On the occasion of the meeting which was held at the Mansion House on March 11th to consider the Chicago Exhibition, those present were given to understand that foreign manufacturers would be allowed to label their wares with the selling prices inclusive and exclusive of duty. Upon the very same day, however, that this powerful inducement to exhibit was being dangled before the Mansion House gathering, Mr. Geo. R. Davis, Director-General of the Exhibition, was penning the following letter to Mr. William F. Wharton, Acting Secretary of State:—

Sir,—I have the honour to acknowledge the receipt of your letter of March 2nd, enclosing a copy of a despatch from the United States Consul at Rheims, making inquiry in regard to price marks which foreign manufacturers of woollen goods may be allowed to place upon their exhibit at the World's Columbian Exposition. In reply to the inquiries of the Consul I have the honour to advise the department that foreign manufacturers, under the regulations heretofore adopted for the management of the Exposition, will be allowed to place upon their exhibits cards bearing their statement of the cost of manufacturing any articles which they may have in their display, and upon the same or other cards they may state the net price which they desire to place upon the said articles for sale in the City of Chicago. Exhibitors who desire to take advantage of this privilege will be strictly required to sell the articles whose prices are so stated to any purchaser who may tender payment for the same, the articles themselves not being deliverable until the close of the Exposition. It would be obviously impracticable to permit exhibitors of foreign manufactures to place upon their wares prices which they might undertake to accept for the same provided no tariff law were in force in the United States.

Just so; exactly what we predicted. We thoroughly agree with the correspondent of our contemporary the *Engineer*, who is of opinion that "very definite information is required on the subject," and advises exhibitors either to insist upon the *understanding* of March last being honourably carried out, or to refrain from exhibiting.

Personal.—Mr. Denny Lane has been elected President of the Incorporated Gas Institute.

Taunton.—At a Town Council meeting last week it was resolved, by 10 votes to 5, to purchase the Taunton Electric Light Works, at a cost of £9,300.

Pretoria (Transvaal).—The Johannesburg *Star* states that the streets of Pretoria were experimentally lighted up for the first time by electricity on May 21st.

Electric Launches in Germany.—The Allgemeine Elektricitäts Gesellschaft is about to build a number of electric launches to run on the Wannsee, near Berlin.

Burnley.—On Tuesday Mr. Arnold conducted a Local Government Board inquiry relating to the application of the Council for permission to borrow £29,000 for a scheme of electric lighting.

The Niagara Falls Power Plant.—Two 5,000 H.P. turbines have been ordered by the Cataract Construction Company from Fœsch and Ficcard, of Geneva, Switzerland, for the Niagara Falls power plant.

Interurban Telephony.—Dunkerque and Marseilles, which are some 550 miles apart, will shortly be placed in telephonic communication. St. Petersburg and Moscow (409 miles) are to be connected by telephone this summer.

Digitized by Google

Obituary.—The death of Mr. George F. Green from intermittent fever is announced. Mr. Green was 60 years of age, and is reputed to have invented the electric street car. He was working on a new electric car at the time of his death.

Cable Restorations:—

	Interrupted	Restored
Bissao-Bolama	April 23, 1892.	June 21, 1892.

All cable routes are at time of going to press in good working order.

Lightning.—During a recent storm at Chicago some 50 persons took refuge in the corridors of the Grant Monument, Lincoln Park. Shortly afterwards the lightning struck the monument. Two men and one woman were killed on the spot, and other persons seriously injured.

Islington.—At the last meeting of the Islington Vestry the Electric Lighting Committee presented a recommendation that a Provisional Order authorising the Vestry to supply electricity should be applied for. The Committee have come to the conclusion that it is possible to give the supply at 5d. per unit.

Cologne Central Station.—On Friday, the 17th inst., this central station was visited by a deputation from the Leicester Gas Committee, who were present during the operation of switching a 150-H.P. alternator into parallel with a 500-H.P. machine, an operation at which Mr. Nikola Tesla was also present.

Société Internationale des Electriciens.—Members of this Society, of which Mr. R. Aylmer, M.Inst.C.E., is hon. secretary and treasurer in this country, are requested to note that the Society's office has been moved from 42, Parliament-street, to 47, Victoria-street, S.W., and that the registered telegraphic address is "Leclanché, London."

Society of Arts.—Among the silver medals awarded this session by the Council are the following:—Prof. Silvanus P. Thompson, F.R.S., for his Paper on "Measurement of Lenses;" Mr. G. H. Robertson, F.C.S., for his Paper on "Secondary Batteries;" Captain W. de W. Abney, C.B., F.R.S., for his Paper on "Colour Blindness."

Mean Spherical Candle-power.—It has been pointed out by Mr. G. W. Patterson, Jun., of the University of Michigan, that the method for finding mean spherical candle-power, given on page 13 (*The Electrician*, May 6, 1892), is erroneous. The method of M. Rousseau is given in Palaz's *Photometrie Industrielle*, page 16, as well as in Gerard's *Leçons*, Vol. II., p. 298.

Ballarat School of Mines.—A department of electrical engineering has recently been added to this institution. It is under the direction of Mr. J. A. Dawson, who has wired a portion of the school and installed the electric light, the current being furnished by a Weston compound-wound dynamo in the laboratory. The course of instruction for this department extends over two years.

The Proposed Mont Blanc Observatory.—According to *La Lumière Electrique*, M. Janssen is about to renew his efforts to get an observatory constructed on Mont Blanc. The structures erected before the winter set in have not been injured. An observatory of wood is to be constructed at Chamounix, and transported piece by piece to the summit. Atmospheric electricity observations will be made.

The Electric Railway Bills.—The Baker-street and Waterloo and Great Northern and City Electric Railway Bills have been referred to a Committee of the House of Lords, consisting of the Marquis of Waterford (Chairman), the Marquis of Breadalbane, Lord Norton, Lord Wimborne, and Lord Magheramorne. The Committee held its first sitting yesterday (Thursday), and a report of the proceedings will be found in our present issue.

Military Projectors.—The French military authorities have recently been experimentally verifying the extraordinary immunity from rifle fire enjoyed by powerful projectors, a fact first brought out in this country some years ago. At the camp at Satory a military projector was set up on the rifle range, and after 175 rounds had been fired at it was practically uninjured. Only one bullet had hit it, and this had merely pierced the case.

Yarmouth.—At the last meeting of the Town Council it was agreed that Messrs. Crompton and Co., Messrs. J. E. H. Gordon and Co., Messrs. Woodhouse and Rawson, Messrs. Hammond and Co., the Planet Electrical Engineering Company, and the Brush Company should be asked to submit schemes with estimates; and that the Electric Lighting Committee should be authorised to employ a consulting engineer to advise them on the specifications and tenders.

Imperial Telegraphic Communication.—At the second Congress of the Chambers of Commerce of the Empire, which will be held at the end of the present month, Sir George Baden Powell will move "That, in the opinion of this Congress, the extension of direct telegraphic communication between the component parts of the British Empire will facilitate defence, promote trade and investments, emphasise community of interests, and generally stimulate the development and consolidation of the Empire."

The Central London Railway.—The Select Committee of the House of Commons, to whom was referred all the London electric railway schemes, having declined to consider in the present Parliament the scheme promoted by the Central London Railway Company to extend their authorised railway from the Mansion House to Liverpool-street Station, the promoters have come to an arrangement with the whole of the opponents, whereby no further opposition will be offered to this extension in either House.

The Société d'Aluminium de Neuhausen.—According to the report of this concern the gross profits of the past twelve months amounted to over £12,000, and the net profits to £6,650, while the market price of aluminium was reduced from 1,900fr. to 625fr. per 100 kilogrammes (7s. to 2s. 6d. per lb.). At the beginning of last year £2,200 of aluminium was being sold per month, while at the end of the year the figure was £5,200. The Neuhausen works can turn out 20 tons of aluminium a month if necessary.

The Paris Electricity Supply Companies.—A committee of the Paris municipality has decided to recommend the prolongation of the electric lighting concessions from 18 to 43 years; the companies, in return for this prolongation, to reduce the maximum price of the hectowatt-hour from 15 to 13 centimes. If, however, the municipality should decide on the purchase of the electric lighting concerns compensation will only be accorded on the basis of the original eighteen-year grant. The price of the plant itself to be fixed by an expert.

Worcester.—At the last meeting of the Town Council it was decided, after considerable discussion, by 28 votes to 10, to accept the Brush Company's tender, subject to obtaining the sanction of the Local Government Board to the requisite loan, and subject to a report from the Watch Committee as to (1) whether provision should be made for steam power only, or steam power and water power combined; (2) whether provision should be made for street lighting. The revised Brush tender amounts to £15,980, and with street lighting will be £22,680.

Proposed Electric Lighting of the Thames Embankment.—At the last meeting of the London County Council the Highways Committee presented a report on the proposal to substitute electricity for gas on the Thames Embankment. They recommended that it be referred to the Highways Committee to carry out, at a cost not exceeding £10,000, an electric installation, with the necessary plant, for the lighting of the carriage ways, footways, and parapet wall of the Victoria Embankment. The consideration of the matter was adjourned for a week.

Exeter.—At the last meeting of the Town Council the Mayor said that he regretted the Council had not been able to see their way to adopt the electric light. But he thought they could not now afford an extra outlay of £392. 17s. 4d. for a light which might not suit the streets of the city. Several councillors objected to a seven years' contract with the Gas Company, and ultimately it was decided that unless the Gas Company were prepared to contract on the same terms for three or five years the Council would give notice to terminate their contract at Michaelmas next.

The Western Union and Bell Telephone Companies.—The general public, says the *Western Electrician*, will derive some

Digitized by Google

satisfaction from the fact that the Bell Telephone Company and the Western Union Telegraph Company are engaged in a legal warfare over the disposition of profits of the former Company. It seems to be the general impression that it is a good thing to get up a fight between these powerful corporations, even though the public is not directly benefited thereby. The idea of making one or both of these great corporations yield a part of the enormous revenues derived from the business has a peculiar charm for the average American.

Electrical Communication with Lightships and Rock Lighthouses.—The Royal Commission appointed to inquire into the question of telegraphic communication with the lighthouses and light vessels around the coasts of the United Kingdom held a preliminary meeting on Saturday last, at 21, Northumberland-avenue, under the presidency of the Earl of Mount Edgcumbe. The other Commissioners are—Sir E. Birkbeck, M.P., Admiral Sir F. L. M'Clintock, Vice-Admiral Sir George Nares, Mr. J. C. Lamb, Mr. R. C. Munro-Ferguson, M.P., Mr. Edward Graves, Mr. J. A. Kempe, Mr. H. L. Mulholland, M.P., and Mr. Garnham Roper, secretary. The Commission will not meet again until the end of July.

Platinum.—Canadian platinum ore, as a commercial article, says the *Engineering and Mining Journal*, is entirely the product of British Columbia. In association with alluvial gold it has been met with in a number of the streams of that province. Placer mining in the Tulameen district yields both gold and platinum, the latter being found, like the gold, in grains and small nuggets. A notable quantity of platinum has already been obtained from this district. One firm in the United States claims to have purchased within the last year or two fully 2,000oz. of British Columbia platinum, and it is well known that a portion of the yield of this district has found its way to the London market. An increase of output may be expected, as the Tulameen Hydraulic and Improvement Company has made preparations to begin hydraulic mining on a large scale.

Electrical Transmission of Power in Switzerland.—An important electrical plant, says the Zürich correspondent of *Industries*, is about to be erected for the transmission of power at Albino. The waters of the Serio are to be stored by a dam 374ft. long, and of a height of 8·2ft. The water will then enter into a canal 2,624ft. long, and will be conveyed by a conduit, 1,805ft. long and 6·9ft. diameter, to the turbines at Cene, a total fall of 49ft. being obtained. There will be three turbines, each of 325 H.P., made by Messrs. Escher, Wyss, and Co. The armatures of the 1,500-volt continuous-current dynamos are placed on the vertical shafts of the turbines. The power will be transmitted a distance of about two miles to the spinning and weaving establishment of Honegger, Spoerry, and Co. The electric plant for this installation is being furnished by the Oerlikon Works.

Mr. Samuel Varley.—A meeting, attended by Messrs. R. E. Crompton, T. E. Gatehouse, W. A. Gorman, Prof. D. E. Hughes, Mr. T. Parker, Major Flood Page, Messrs. A. Stroh and J. W. Swan, was recently held at the rooms of the Institution of Electrical Engineers, for the purpose of discussing the best method of recognising the great services of Mr. Samuel Varley to the electrical industry. The meeting was unanimously of opinion that the services of Mr. Samuel Varley to the electrical industry deserved substantial recognition, and that everyone interested in electrical engineering should be invited to join the Committee for the purpose of discussing the best form that this recognition should take, and that a draft circular should be prepared ready for submission to a meeting of the Institution of Electrical Engineers at 28, Victoria-street, on Friday, July 1st, at 4 o'clock.

London County Council Overhead Wires Bye-Laws.—On Monday a conference took place between the officials of the Board of Trade and the representatives of the London County Council, the Commissioners of Sewers, the Telephone Companies, and several of the Vestries of the metropolis, with reference to the London County Council bye-laws, made in pursuance of the London Overhead Wires Act, of 1891 (see *The Electrician*, Vol. XXVIII., p. 149). The Board of Trade was represented by Sir Courtenay Boyle, Mr. Gray (Counsel for the Board), Sir Thomas Blomefield, Major Cardew, and Mr. W. H. Preece. Among the parties who had objections were Mr. Meadows White, Q.C., Mr. Bloxland, Mr. Hertslet and Sir Benjamin Baker, for the County Council; and Messrs. J. S. Forbes, Winterbotham, Wallace, Wilkins, Gaine, Baylis, and Col. Heywood represented other parties. The rules were gone through *seriatim*, and at the close of a five hours' sitting Sir Courtenay Boyle intimated that the Board of Trade would communicate to the County Council its approval or otherwise.

Strike of Spanish Telegraphists.—The telegraphists throughout Spain have struck work on account of the amalgamation of the telegraph and postal services. The telegraph staff have to pass an examination before being appointed, and they have never taken any part in political matters, whereas the post-office officials in most cases owe their appointments to political influence. At Madrid the Government has replaced the officials on strike by military operators, but telegraphic communication with the provinces is practically suspended. For instance, there are 21 repetitions between Bilbao and Madrid. A Reuter's telegram dated Bilbao, June 22, says:—The strike of telegraph operators in this country is complete. There is not a single line working in the interior of Spain, and the only means of communication with foreign countries is by the cables from Bilbao, Barcelona, Vigo, and Lisbon. There seems a probability of the strikers establishing their claims and forcing the Government to concede their terms. Nearly 2,800 operators are idle, the majority being present in the telegraph offices while refusing to touch their instruments.

Electricity in Warfare.—In a recent article in the *St. James's Gazette* a "Military Optimist" writes:—"Important experiments have been made with the electric search light as an aid to night operations; while the telegraph battalion has done some thoroughly good and novel things. That was no insignificant feat performed the other night, when an extensive cable was laid rapidly over the roughest possible ground (in the dark, mind!) and enabled the lieutenant-general not only to find a lost brigade, but to control the simultaneous advance and attack of three separated brigades on an earthwork at midnight. The telegraph, in fact, rendered a most difficult and doubtful operation comparatively easy and certain. At the manœuvres last autumn, too, a highly useful attempt was made to produce on a map at head quarters a plan of battle step by step as it progressed many miles away, by means of reports wired from the field. The attempt did not succeed, because the maps available were not on a sufficient scale; but the feasibility of the plan was demonstrated, while its value to a general directing operations over a wide field is obvious enough. With large-scale maps, a balloon, and increased observing staff, it should be made a most important aid to the strategist and the tactician."

Electrical Engineering at University College.—For some time past the Council of University College have been desirous of extending the provision made for teaching mechanical and electrical engineering. The present provision for teaching these subjects is, however, no longer adequate. The Council have therefore resolved to build better and more commodious engineering and electrical laboratories and lecture rooms. They have accordingly instructed their architect, Prof. Roger Smith, to prepare plans and specifications for a new technical laboratory. These designs have been very carefully prepared in accordance with the views of Profs. T. H. Beare and J. A. Fleming. To fit up that part of the proposed laboratory specially set apart for electrical engineering, Prof. Fleming asks for the modest sum of £2,010. The Council do not at present see their way to incur this additional expenditure over and above the cost of the buildings, and yet it is absolutely essential to the completion of the project. The Council have, therefore, recommended this part of the proposed work to the notice and liberality of those who may be disposed to help. It is to be hoped that this good work will commend itself especially to past students and friends of University College, and that the necessary help will be forthcoming. Donations should be sent to the Secretary of University College, London, marked "Electrical Apparatus Fund."

ELECTROMAGNETIC THEORY.—XXXI.

BY OLIVER HEAVISIDE.

(*Continued from page 139.*)

§145. The elastic solid with two elastic constants (k and n) has not been found sufficiently elastic to supply a thoroughly satisfactory analogy with Maxwell's ether, though partial analogies may readily be found. Other kinds of elasticity than resistance to compression and distortion, and other kinds of resistance than elastic resistance, present themselves to the consideration of searchers for analogies between the propagation of disturbances in Maxwell's ether and in the brutally simple elastic solid of theory, which is, however, known to fairly represent real solids within a certain range.

There are four distinct ideas involved in the displacement of a small portion of matter, viz., the translation as a whole, the rotation as a whole, the change of size, and the change of shape. These separate themselves from one another naturally. As regards the mere translational motion, if it be only inertially resisted, we have the equation of motion

$$\mathbf{f}+\mathbf{F}=\rho\frac{\delta\mathbf{q}}{\delta t}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (306)$$

where ρ is the density, $\mathbf{q}$ the velocity, $\mathbf{f}$ impressed force (per unit volume), $\mathbf{F}$ the force arising from the stress associated with the strain (including rotation, distortion, and expansion), and $\delta/\delta t$ the time-differentiator for moving matter. This equation is constructed on simple Newtonian principles. We may, however, wish to have elastic and frictional resistance to translation, as well as inertial resistance. Then generalize the above to

$$\mathbf{f}+\mathbf{F}=\left(\rho_0+\rho_1\frac{d}{dt}+\rho_2\frac{d^2}{dt^2}\right)\mathbf{G}, \quad . \quad . \quad . \quad (307)$$

where $\mathbf{G}$ is the displacement, when small departures from equilibrium are concerned. Here ρ_2 is the ρ of (306), ρ_1 is the frictionality (Lord Kelvin's word for coefficient of friction), and ρ_0 is an elastic constant. The displacement from equilibrium calls into action a back force $\rho_0\mathbf{G}$ proportional to the displacement, with storage of potential energy; a force $\rho_1\dot{\mathbf{G}}$ proportional to the velocity, with waste of energy; and a force $\rho_2\ddot{\mathbf{G}}$ proportional to the acceleration, with associated kinetic energy. The potential energy is $\frac{1}{2}\rho_0\mathbf{G}^2$, the rate of waste $\rho_1\dot{\mathbf{G}}^2$, and the kinetic energy $\frac{1}{2}\rho_2\dot{\mathbf{G}}^2$.

As regards the force $\mathbf{F}$, this is given by (284), when the stress is irrotational, and the elastic constants are n and k. But, in general, we may proceed thus. First separate the rotation from the strain vector. We have

$$\begin{aligned}\mathbf{N}\nabla.\mathbf{G}&=\tfrac{1}{2}(\mathbf{N}\nabla.\mathbf{G}+\nabla.\mathbf{N}\mathbf{G})+\tfrac{1}{2}(\mathbf{N}\nabla.\mathbf{G}-\nabla.\mathbf{N}\mathbf{G})\\&=\mathbf{p}_\mathbf{N}-\tfrac{1}{2}\mathrm{V}\mathbf{N}\operatorname{curl}\mathbf{G}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (308)\end{aligned}$$

Here $\mathbf{N}\nabla.\mathbf{G}$ means the variation of displacement per unit distance along $\mathbf{N}$, which is any unit vector, so that by giving $\mathbf{N}$ all directions (practically only three) the complete state of strain is known. This strain vector is above analysed into the strain $\mathbf{p}_\mathbf{N}$ without rotation, and the second part depending upon rotation. But $\mathbf{p}_\mathbf{N}$ includes the expansion, as well as the distortion, or mere change of shape. To exhibit the distortion without expansion, one-third of the expansion (vectorised) must be deducted. Thus

$$\mathbf{N}\nabla.\mathbf{G}=(\mathbf{p}_\mathbf{N}-\tfrac{1}{3}\mathbf{N}\operatorname{div}\mathbf{G})+\tfrac{1}{3}\mathbf{N}\operatorname{div}\mathbf{G}-\tfrac{1}{2}\mathrm{V}\mathbf{N}\operatorname{curl}\mathbf{G} \quad (309)$$

shows the separation of the strain into a distortion (without change of size), an expansion, and a rotation, which are naturally independent.

If distortion, expansion, and rotation are all elastically resisted, three independent elastic constants (in an isotropic medium) intervene between the above strain and the corresponding stress $\mathbf{P}_\mathbf{N}$ upon the plane whose normal is $\mathbf{N}$. To obtain $\mathbf{P}_\mathbf{N}$, multiply the distortional part by $2n$, the expansional part by $3k$, and the rotational part by 2ν, and add the results. Thus,

$$\mathbf{P}_\mathbf{N}=2n(\mathbf{p}_\mathbf{N}-\tfrac{1}{3}\mathbf{N}\operatorname{div}\mathbf{G})+\mathbf{N}k\operatorname{div}\mathbf{G}-\nu\mathrm{V}\mathbf{N}\operatorname{curl}\mathbf{G}. \quad (310)$$

Compare with (290). Here n and k are as before, whilst ν is a new elastic constant connected with the rotation, and which was previously assumed to have the value zero. That is, there was assumed to be no resistance to rotation. The corresponding torque is

$$\mathbf{S}=2\nu\operatorname{curl}\mathbf{G}. \quad . \quad . \quad . \quad . \quad . \quad (311)$$

With the rotational part of the stress is also associated translational force, given by

$$-\operatorname{curl}\tfrac{1}{2}\mathbf{S}=-\nu\operatorname{curl}^2\mathbf{G}. \quad . \quad . \quad . \quad (312)$$

Adding this on to the former expression for the force (or deriving the force from (310) directly), we find that

$$\mathbf{F}=n(\nabla^2\mathbf{G}+\tfrac{1}{3}\nabla\operatorname{div}\mathbf{G})+k\nabla\operatorname{div}\mathbf{G}-\nu\operatorname{curl}^2\mathbf{G} \quad (313)$$

represents the translational force to be used in the equation of motion (307). We should notice here that the quantity $k\operatorname{div}\mathbf{G}$ in (310) represents a uniform tension. It equals one-third of the sum of the normal tractions on any three mutually perpendicular planes. Its negative represents the pressure, or $p=-k\operatorname{div}\mathbf{G}$. Now when there is incompressibility, k is infinite, and $\operatorname{div}\mathbf{G}$ is zero. But their product usually remains finite. So in any case we may replace the k term in (310) by $-\mathbf{N}p$, and the k term in (313) by $-\nabla p$.

The energy of the strain is

$$\mathrm{U}=\tfrac{1}{2}(\mathbf{P}_1\nabla_1+\mathbf{P}_2\nabla_2+\mathbf{P}_3\nabla_3)\mathbf{G}, \quad . \quad . \quad . \quad (314)$$

or one-half the sum of the scalar products of the stress vector and the strain vector for three perpendicular planes, $\mathbf{P}_1$, $\mathbf{P}_2$, $\mathbf{P}_3$ being the stresses on the $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$ planes respectively. On reckoning up, by (310), (309), we find the energies of expansion, rotation, and distortion are all independent, and that U is their sum, given by

$$\mathrm{U}=n[\mathbf{p}_1^2+\mathbf{p}_2^2+\mathbf{p}_3^2-\tfrac{1}{3}(\operatorname{div}\mathbf{G})^2]+\tfrac{1}{2}k(\operatorname{div}\mathbf{G})^2+\tfrac{1}{2}\nu(\operatorname{curl}\mathbf{G})^2, \quad (315)$$

where the ν term is the energy of rotation ($=\frac{1}{2}$ torque $\times$ rotation), the k term is the energy of expansion, and the n term the energy of distortion.

Now the stress (310) is derived from the strain (309) by the introduction of elastic resistances only. There is, however, no reason why we should limit the nature of the resistance in this way. Consider the n term only for example, relating to distortion. There may also be dissipative or frictional resistance to distortion. To exhibit it, change n to $n_0+n_1(d/dt)$ in (310), (313). Then n_0 will be the rigidity and n_1 the viscosity, or coefficient of frictional resistance to distortion. For instance, if we abolish n_0 and ν, and retain ν_1 and k, we have the stress in a real viscous fluid according to Stokes's theory. It may be that there is not a complete disappearance of the rigidity in a fluid; if so, then retain both n_0 and n_1. When the rigidity is marked, as in a solid, n_0 is the important part of n; whilst in a fluid it is the other part. It is, however, not at all to be expected that the expression of the viscosity of solids by n_1, if true at all, would extend beyond the small range of approximately perfect elasticity. Lord Kelvin's experiments on the subsidence of the oscillations of wires tended to show that a different law was followed than that corresponding to the viscosity of fluids, and that elastic fatigue was concerned in the matter.

There may also be, conceivably, inertial resistance to distortion, and not only elastic, but also frictional and inertial resistance to rotation, and the same with respect to expansion. These will be brought in by generalising the three elastic constants k, n, and ν of (310) thus:—

$$\left.\begin{aligned}k&=k_0+k_1(d/dt)+k_2(d^2/dt^2),\\n&=n_0+n_1(d/dt)+n_2(d^2/dt^2),\\\nu&=\nu_0+\nu_1(d/dt)+\nu_2(d^2/dt^2),\end{aligned}\right\} \quad . \quad . \quad (316)$$

where of the nine coefficients on the right side, the first three are elastic constants, the second three dissipative constants, the last three inertial constants; the elastic constants involving potential energy, the dissipative constants waste of energy, and the inertial constants kinetic energy, similarly to (307) as regards translation. Out of these twelve constants only four are in use, or seven, if ν_0 and ν_1, and ρ_1 be included, which additionals have been speculatively employed. This does not represent finality by any means; but sufficient has been said on the subject of generalising the elastic constants to emphasize

Digitized by Google

the fact that there is plenty of scope for investigation in the theory of the motion of media of unknown internal constitution, which, externally viewed, involve the four elements translation, rotation, expansion and distortion.

The activity of the stress vector $\mathbf{P}_N$ is $\mathbf{P}_N\mathbf{q}$, and the flux of energy is (*see* §§ 68, 72 also), if q be the speed, or tensor of the velocity.

$$\mathbf{q}(U+T)-\mathbf{Q}_q q, \quad . \quad . \quad . \quad . \quad . \quad (317)$$

where U and T are the complete potential and kinetic energies, per unit volume, and $\mathbf{Q}_N$ is the stress conjugate to $\mathbf{P}_N$, to obtain which change the sign of the last (rotational) term in (310). The convergence of the energy flux represents the work done and stored or wasted in the unit volume. Considering the term $\mathbf{Q}_q q$ only (the rest being the convective flux of energy), its convergence is

$$\begin{aligned}\operatorname{div}(\mathbf{Q}_1 q_1+\mathbf{Q}_2 q_2+\mathbf{Q}_3 q_3)&=\nabla_1(\mathbf{P}_1\mathbf{q})+\nabla_2(\mathbf{P}_2\mathbf{q})+\nabla_3(\mathbf{P}_3\mathbf{q})\\&=q_1\operatorname{div}\mathbf{Q}_1+q_2\operatorname{div}\mathbf{Q}_2+q_3\operatorname{div}\mathbf{Q}_3+\mathbf{Q}_1\nabla q_1+\mathbf{Q}_2\nabla q_2+\mathbf{Q}_3\nabla q_3\\&=\mathbf{F}\mathbf{q}+(\mathbf{P}_1\nabla_1+\mathbf{P}_2\nabla_2+\mathbf{P}_3\nabla_3)\mathbf{q}, \quad . \quad . \quad . \quad (318)\end{aligned}$$

where $\mathbf{F}$ is the force as in (313). $\mathbf{F}\mathbf{q}$ is the translational activity, which may, by (307), be employed in increasing kinetic and potential energy or be wasted. The rest represents the rate of increase of the sum of the three potential energies when there is merely elastic resistance; but if we use (316) we obtain also the sum of the rates of waste of energy, through k_1, n_1, ν_1, and also the rate of increase of the sum of the kinetic energies, through k_2, n_2, ν_2.

Thus we have, by (310),

$$\begin{aligned}&(\mathbf{P}_1\nabla_1+\mathbf{P}_2\nabla_2+\mathbf{P}_3\nabla_3)\mathbf{q}\\&=\frac{d\mathbf{q}}{dx}\Big(2n(\mathbf{p}_1-\tfrac{1}{3}\mathbf{i}\operatorname{div}\mathbf{G})+k\mathbf{i}\operatorname{div}\mathbf{G}-\nu\mathbf{V}\mathbf{i}\operatorname{curl}\mathbf{G}\Big)\\&+\frac{d\mathbf{q}}{dy}\Big(2n(\mathbf{p}_2-\tfrac{1}{3}\mathbf{j}\operatorname{div}\mathbf{G})+k\mathbf{j}\operatorname{div}\mathbf{G}-\nu\mathbf{V}\mathbf{j}\operatorname{curl}\mathbf{G}\Big)\\&+\frac{d\mathbf{q}}{dz}\Big(2n(\mathbf{p}_3-\tfrac{1}{3}\mathbf{k}\operatorname{div}\mathbf{G})+k\mathbf{k}\operatorname{div}\mathbf{G}-\nu\mathbf{V}\mathbf{k}\operatorname{curl}\mathbf{G}\Big)\\&=2n(\mathbf{p}_1\nabla_1\mathbf{q}+\mathbf{p}_2\nabla_2\mathbf{q}+\mathbf{p}_3\nabla_3\mathbf{q})-\frac{2n}{3}\operatorname{div}\mathbf{D}\operatorname{div}\mathbf{q}\\&\qquad+k\operatorname{div}\mathbf{D}\operatorname{div}\mathbf{q}+\nu\operatorname{curl}\mathbf{D}\operatorname{curl}\mathbf{q} \quad . \quad . \quad . \quad (319)\end{aligned}$$

Take for illustration, the rotational term $\nu\operatorname{curl}\mathbf{D}\operatorname{curl}\mathbf{q}$. This is simply $(d/dt)\{\frac{1}{2}\nu(\operatorname{curl}\mathbf{G})^2\}$, or the rate of increase of the rotational energy, when ν is a constant, but when we use the last of (316) it becomes

$$\frac{d}{dt}\Big(\tfrac{1}{2}\nu_0(\operatorname{curl}\mathbf{G})^2\Big)+\tfrac{1}{2}\nu_1(\operatorname{curl}\mathbf{q})^2+\frac{d}{dt}\Big(\tfrac{1}{2}\nu_2(\operatorname{curl}\mathbf{q})^2\Big), \quad (320)$$

showing the rates of increase of potential and kinetic energy, and the rate of waste (the middle term) due to rotational friction. Similarly as regards the other terms in (319). The expansion terms give

$$\frac{d}{dt}\Big(\tfrac{1}{2}k_0(\operatorname{div}\mathbf{G})^2\Big)+\tfrac{1}{2}k_1(\operatorname{div}\mathbf{q})^2+\frac{d}{dt}\Big(\tfrac{1}{2}k_2(\operatorname{div}\mathbf{q})^2\Big), \quad . \quad (321)$$

where the middle term is the rate of waste, and the others rates of increase of potential and kinetic energies. Finally, the distortional terms of (319) give

$$\begin{aligned}&\frac{d}{dt}n_0\Big(\mathbf{p}_1^2+\mathbf{p}_2^2+\mathbf{p}_3^2-\tfrac{1}{3}(\operatorname{div}\mathbf{G})^2\Big)\\&+2n_1\Big(\dot{\mathbf{p}}_1^2+\dot{\mathbf{p}}_2^2+\dot{\mathbf{p}}_3^2-\tfrac{1}{3}(\operatorname{div}\mathbf{q})^2\Big)\\&+\frac{d}{dt}n_2\Big(\dot{\mathbf{p}}_1^2+\dot{\mathbf{p}}_2^2+\dot{\mathbf{p}}_3^2-\tfrac{1}{3}(\operatorname{div}\mathbf{q})^2\Big), \quad . \quad . \quad (322)\end{aligned}$$

where the first line is the rate of increase of the potential energy, the second line the frictional rate of waste, and the third line the rate of increase of kinetic energy. We thus complete the energy relations of the stress with the generalised elastic constants, and so far as small motions are concerned, the equations are manageable.

§ 146. Comparisons between the propagation of electromagnetic disturbances in Maxwell's ether, or in a homogeneous isotropic dielectric, whether conducting or not, and the propagation of motion in an elastic solid, either simple or generalised, may be made in a variety of ways. They all break down sooner or later, but are nevertheless useful as far as they go. A few cases will be now considered, based on the preceding. First take the case of a non-conducting dielectric at rest, and compare it with the regular elastic solid made incompressible by infinite resistance to compression. The incompressibility includes inexpansibility.

In the dielectric we have, if p stands for d/dt, for convenience,

$$\operatorname{curl}(\mathbf{H}-\mathbf{h})=cp\mathbf{E},\ \operatorname{curl}(\mathbf{e}-\mathbf{E})=\mu p\mathbf{H}, \quad . \quad (323)$$

the circuital equations connecting $\mathbf{E}$ and $\mathbf{H}$ (§§ 38, 24, 66), where $\mathbf{e}$ and $\mathbf{h}$ are impressed, and μ, c are the inductivity and permittivity. Now, the equation of motion in an incompressible solid is, by (273),

$$\mathbf{f}_1=(\rho p^2-n\nabla^2)\mathbf{G}=\Big(\rho p-\frac{n}{p}\nabla^2\Big)\mathbf{q}, \quad . \quad . \quad (324)$$

where ρ and n are the density and rigidity, $\mathbf{G}$ the displacement, $\mathbf{q}$ the velocity, and $\mathbf{f}_1$ the circuital part of the impressed forcive, the divergent part being inoperative. Or we may take the impressed forcive to be circuital to begin with.

Now, let $\mathbf{h}=0$, and $\mathbf{e}$ be finite. If it has no curl, it does nothing, as before shown (§ 89). The source of disturbance is $\operatorname{curl}\mathbf{e}$. This being the case in the dielectric, and $\mathbf{f}_1$ being the source of motion in the solid, it will be convenient to take $\mathbf{f}_1$ and $\operatorname{curl}\mathbf{e}$ as corresponding. Let the latter be (temporarily) $\mathbf{f}$. Then (323) gives (remembering that $\operatorname{div}\mathbf{H}=0$),

$$\mathbf{f}=\mu p\mathbf{H}+\operatorname{curl}\mathbf{E}=\mu p\mathbf{H}+\operatorname{curl}^2\mathbf{H}/cp,$$

or,

$$\mathbf{f}=\Big(\mu p-\frac{\nabla^2}{cp}\Big)\mathbf{H}=\Big(\mu p^2-\frac{\nabla^2}{c}\Big)\frac{\mathbf{H}}{p}. \quad . \quad . \quad (325)$$

Comparing this with the second of (324), and assuming the equality of $\mathbf{f}$ and $\mathbf{f}_1$, we see that $\mathbf{H}$ is velocity, μ density, c^{-1} rigidity; and so on. $\mathbf{H}/p$ means the time-integral of $\mathbf{H}$. Or, more explicitly, let $\mathbf{Z}$ be the time-integral of $\mathbf{H}$, so that $\mathbf{H}=p\mathbf{Z}$; then

$$\mathbf{f}=(\mu p^2-c^{-1}\nabla^2)\mathbf{Z}, \quad . \quad . \quad . \quad . \quad (326)$$

which compares with the first of (324). Thus

	$\mathbf{Z}=\mathbf{H}/p$	corresponds to	$\mathbf{G}$,	(spacial displ),
(mag. force)	$\mathbf{H}=p\mathbf{Z}$	,,	$\mathbf{q}$,	(velocity),
(el.current)	$\operatorname{curl}\mathbf{H}$	,,	$\operatorname{curl}\mathbf{q}$,	(2 × spin),
(el. displ.)	$\mathbf{D}=c\mathbf{E}$	,,	$\operatorname{curl}\mathbf{G}$,	(2 × rotation),
(inductivity)	μ	,,	ρ,	(density),
(permittivity)	c	,,	$1/n$,	(compliancy),
(mag. source)	$\mathbf{f}=\operatorname{curl}\mathbf{e}$	,,	$\mathbf{ff}$,	(impd. force),
(mag. energy)	$\frac{1}{2}\mu\mathbf{H}^2$	,,	$\frac{1}{2}\rho\mathbf{q}^2$,	(kin. energy).

This is, as far as it goes, an excellent analogy, particularly on account of its directness and ease of application, and on account of the similarity of sources. The disturbances of $\mathbf{H}$ generated by $\mathbf{f}$ in the dielectric and propagated away at speed $(\mu c)^{-\frac{1}{2}}$ are precisely represented by the velocity generated by similarly distributed impressed Newtonian force, which is propagated in the same manner through the solid at the equivalent speed $(n/\rho)^{\frac{1}{2}}$. Of course the correspondence at similar moments also applies to the other quantities compared.

But it is imperative (in general) that the motions in the solid should be small. The disturbances should therefore be of the fluctuating or alternating character, so that $\mathbf{Z}$, the time-integral of $\mathbf{H}$, does not mount up. For, correspondingly, if this were allowed, then $\mathbf{G}$ would mount up, and the elastic solid get too much out of shape to allow us to treat d/dt at a fixed point and $\delta/\delta t$ for a moving particle as identical.

Observe also, that the electric energy $\frac{1}{2}c\mathbf{E}^2$ is not matched by the potential energy of distortion; although their total amounts are equal, their distributions are entirely different. This is a fatal failure in detail. Nor have we any right to expect that a scheme like Maxwell's, depending upon rotations, can be perfectly matched by one which depends on shears.

§ 147. Another analogy of the same class is got by making the displacement in the solid represent the time-integral of $\mathbf{E}$ in the dielectric. Thus let $\mathbf{e}=0$ in (323), and $-\operatorname{curl}\mathbf{h}=+\mathbf{g}$. It is now $\mathbf{g}$ that is the source. Eliminate $\mathbf{H}$ between the two equations (323). We get

$$cp\mathbf{E}+\mathbf{g}=\operatorname{curl}(-\operatorname{curl}\mathbf{E})/\mu p. \quad . \quad . \quad . \quad (327)$$

Digitized by Google

Or, since div $\mathbf{E}=0$ (when there is no electrification)

$$\mathbf{g}=\left(cp-\frac{\nabla^2}{\mu p}\right)\mathbf{E}=\left(cp^2-\frac{\nabla^2}{\mu}\right)\mathbf{A}, \quad . \quad . \quad (328)$$

if $\mathbf{A}=\mathbf{E}/p$, making $\mathbf{E}=p\mathbf{A}$.

Comparing (327) with (324) for the solid, we see that we have $\mathbf{E}$ representing velocity, μ compliancy, c density, and so on, being a general turning over of all the quantities. Thus

$\mathbf{A}=\mathbf{E}/p$	corresponds to	$\mathbf{G}$ (displacement),
μ	,,	n^{-1},
c	,,	ρ,
(el. force) $\mathbf{E}$	,,	$\mathbf{q}$ (velocity),
$\frac{1}{2}c\mathbf{E}^2$	,,	$\frac{1}{2}\rho\mathbf{q}^2$,
$\mathbf{H}$	,,	n curl $\mathbf{G}$,
$-$ curl $\mathbf{h}$	,,	$\mathbf{f}_1$ (circuital impd. force).

The conclusions are similar as regards the generation and propagation of disturbances of the two kinds compared. There is a similar failure to before as regards the energy of distortion. It ought to be the magnetic energy $\frac{1}{2}\mu\mathbf{H}^2$ now, but it is not. This want of correspondence as regards one of the energies will be removed (and can only be removed) by doing away with the rigidity and substituting something else, which must, however, be equivalent in its results as regards the propagation of disturbances from place to place.

[**Corrections.**—In equations (302) and (303), last section, change $-$ to $+$. In second line after equation (305), for (301) read (303).]

(*To be continued.*)

A MODE OF VARYING THE CANDLE-POWER OF ARC LAMPS, ARRANGED TWO IN SERIES ON 110-VOLT CIRCUITS.*

BY P. VITTE.

In many instances it is a useful thing to be able at will to regulate the current taken by arc lamps by merely adjusting a rheostat without touching the mechanism of the lamp itself, and without disturbing the working. I will take the case of two lamps in series on a 110-volt circuit, a problem easily solved, though the conditions to be fulfilled exclude all lamps with series-wound electro-magnets. The lamps employed should have only a single shunt-wound electro-magnet, serving both for striking the arc and for regulation. Such lamps are the Brianne and that of the Société Alsacienne. I used the latter make, and they gave every satisfaction, both from the point of view of striking the arc and of regulation.

I lay stress on the two following statements, well known to all practical men:—(i.) The difference of potential between the two carbons increases in proportion to the length of the arc, and is independent of the value of the current. (ii.) The normal arc practically corresponds to 40 volts within wide limits.

In order to state the case precisely let us take for example an inferior homogeneous 9mm. and a good cored 14mm. carbon, and assume that the current feeding the lamp is 5 amperes. If we suddenly increase the current to 12 amperes by altering the regulating resistance we shall see that the pressure at the lamp terminals does not vary. Strictly speaking, it varies momentarily while the length of the arc is altering, and then immediately returns to its original value, only to increase again as the carbons are consumed. This confirms my first statement. On the other hand, if the lamp mechanism has been set for 40 volts, and if we give the current successive values of 5, 6, 7, 8, 9, 10, 11, and 12 amperes, we shall find that in all cases the arc remains sensibly normal—neither too large nor too small. It is, however, as well to employ carbons suited to the average current for which the lamp is intended. The following are the sizes generally employed:—

6	amperes	9	to 14	mm.	carbons.
9	,,	10	,, 16	,,	,,
12	,,	11	,, 18	,,	,,

In all these different cases we always find that the pressure of 40 volts gives regular results.

When the two lamps have each been adjusted to 40 volts, we shall lose 30 volts in the resistance at 110 volts. It will consequently be sufficient to fit up a hand rheostat, enabling the consumer to run according to his requirements at from 5 to 12 amperes. The efficiency evidently remains the same under all conditions, since the energy lost in the rheostat is always $\frac{30}{110}$ of the total energy supplied. By making these sudden changes from 5 to 12 and from 12 to 5 amperes we obtain lighting effects practically without affecting the regular working of the lamp.

The practical adjustment of two arc lamps of this kind is extremely simple. With 110 volts between the points A and B (*see* Figure), we place the rheostat R, the lamps L and L', the switch C, and an ordinary fuse, all in series. Having closed the switch and struck the arcs, and the rheostat having been adjusted approximately to the current with which we wish to work ($Ri=30$ volts), the first thing to do is to see if the poles are right. The crater, as is well known, ought to be formed at the end of the upper carbon, which has to give out most of the light, and it has, therefore, to be connected to the + terminal. The craters being at the bottom of the upper carbons, we may now proceed to the adjustment. To effect this we begin by lengthening or shortening one of the arcs by manipulating the regulating mechanism, either preventing it from acting or making it act, without troubling ourselves about the current or the other lamp, until the arc under treatment has its normal value, which one can see by the pressure at the terminals, being 40 volts, or by signs which I will detail further on. The first lamp regulating at the required pressure, we can now pass on to the second lamp, upon which we operate in a similar manner. The two lamps being adjusted we go to the rheostat, which enables us to bring the current to the required value.

When an arc is too long the lower carbon flattens, and the arc flares and flickers. When the arc is too short, the lower carbon is surmounted by a tip, and forms a screen in front of the crater, which diminishes the luminous efficiency. With a normal arc the lower carbon is terminated by a rounded knob. Looking perpendicularly at the axis of the carbons, we ought to see a gap of about one millimetre between the two carbons; sometimes a little less, sometimes more (for instance, in 25 ampere arcs). As soon as we exceed 12 amperes we are obliged to adopt somewhat higher terminal pressures than 40 volts. An examination of the arc in the light of the above remarks should be a guide to the electrician.

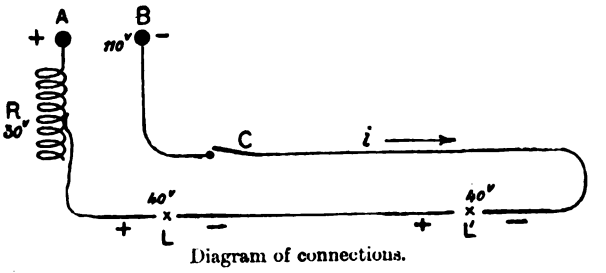

Diagram of connections.

From the point of view of efficiency it is evidently advantageous to have arcs as long as possible. In reality, 40 volts is the average pressure; according to circumstances, we regulate arcs at from 38 to 42 volts. For instance, the mechanician should adjust for 41 volts, the pressure falling at the moment of feeding to 40 volts.

We have

$$110\,\mathrm{V}=\mathrm{R}\,i+\varepsilon+\varepsilon'$$
$$0=\mathrm{R}\,di+d\varepsilon+d\varepsilon'=\mathrm{R}\,di+2\,d\varepsilon$$

since the two lamps are under the same conditions as to consumption. Hence $di=-\frac{2d\varepsilon}{\mathrm{R}}$. The variation of current is less for a given variation of the terminal pressure the greater R is.

If the lamp feeds for a variation of one volt, the maximum variation of current for 10-ampere lamps, with $\mathrm{R}=3$ ohms, will be $\Delta i=\frac{2}{3}$ ampere. In reality, the two lamps rarely feed simultaneously, and it is therefore easy to see that the variations of current are less. The maximum variation of current for the same lamps working at 5 amperes will be $\frac{2}{6}=\frac{1}{3}$ ampere, since $\mathrm{R}=6$ ohms in this instance. We see, therefore, that the relative variation of the current due to feeding remains the same for all values of the current which traverses two given lamps. Two 10-ampere lamps of the type selected for this investigation, running off a 110-volt circuit and absorbing 30 volts in the resistance, keep the current steady to within half an ampere.

To regulate differential lamps arranged two in series on a 110-volt circuit, the following practical rules may be relied on. (1) Owing to the solidarity of the arcs if we lengthen one we shorten the other. The thing to be done is, therefore, to bring the arcs to equality while bearing this fact in mind. (2) If we lengthen the two arcs together the pressure at the lamp terminals increases, and the current diminishes, and inversely if we shorten the two arcs together the pressure at the lamp terminals decreases and the current increases. (3) If we diminish the regulating resistance the pressure at the lamp terminals and the current both increase, and inversely, if we increase the resistances, the pressure at the lamp terminals falls and the current decreases.

By bearing these facts in mind we are able to quickly adjust two differential arc lamps from the point of view of length of arc and of current without too many tentative attempts.

"The Electrician"

ELECTRICAL TRADES' DIRECTORY AND HANDBOOK FOR 1892.

(THE BLUE BOOK.)

THE ONLY RELIABLE DIRECTORY

Published for the Electrical and Allied Trades.

PRICE: 7s. 6d.; post-free, 8s. 3d.; abroad, 8s. 10d.

"DIGEST OF CONTENTS" ON APPLICATION.

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

Vol. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.

Vol. II.—THE APPLICATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

LECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

NOW READY, IN TWO VOLUMES. PROSPECTUSES FREE.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

Several Further Volumes in Active Preparation.

FULL CATALOGUE POST FREE ON APPLICATION.

MICROSCOPE READINGS OF GALVANOMETERS.

Few if any attempts are made in this country to read galvanometer deflections in any other way than by the movement of a needle on a dial, or by the motion of a spot of light on a scale. The former is only suitable for rough instruments, though capable of yielding good results in the hands of trained men, as in the case of the tangent galvanometers of the Post Office; but difficulties of parallax and the need for double readings limit the use of pointers, as a rule, to an accuracy of half a degree. One-tenth of a millimetre may be estimated by a practised observer with a first-rate mirror galvanometer; but between these two there is a wide range of readings which may be filled in by microscope readings. Telescope readings are common on the Continent, but the observer generally sits at a considerable distance from the instrument. There is no reason for this; a microscope and a telescope are essentially identical instruments, and differ only in the focal length of the lenses. Microscopes are largely employed in astronomical work and on surveying instruments, but a more simple arrangement is sufficient for a galvanometer. A flat mirror should be used, and the reflected image of a concentric cylindrical scale should be observed by a short focus telescope or long focus microscope. Instrument makers should turn their attention to the construction of such instruments with large lenses, and giving a wide field.

One of the advantages of galvanometers of the d'Arsonval type lies in the fact that the coil is attached at top and bottom by a wire. This makes the instrument more substantial, and at the same time renders the coil less liable to side motions than is the case with the needle of an ordinary THOMSON galvanometer. The motion of the spot of light on a scale is entirely due to the angular motion of the needle,

Digitized by Google

as side motions are not magnified by the mirror method. Unfortunately, this is not the case if a microscope is used to measure the movement of the extremity of a short pointer attached to the needle. The microscope method would be far more sensitive than the mirror method, and would long ago have superseded it in laboratories were it not for the fact that lateral motions of the needle (due to pendulum action) produce as great, if not greater, effect than the angular motions to be measured. But if these side motions can be got rid of by the use of very light coils suspended at both ends, or in any other way, the microscope method is in many ways preferable to the mirror or telescope methods, the use of either of which practically so enlarges the instrument that it occupies a considerable space. The Cardew voltmeter, or the sag form of hot wire voltmeter, seem to be instruments specially adapted to the microscope, and other examples could no doubt be found. The disadvantage of using any mechanical method of magnifying the indications of an instrument consists in the delicacy of the adjustment, or in the backlash of the parts. These defects are not found in optical methods. For practical instruments, telescopes are out of the question; but a cheap form of microscope does not appear so, and it is remarkable that so little attention has been devoted to its use.

Rather too much prominence has been given of late to standard galvanometers, which are carefully fixed in place and never moved, or to very sensitive or special forms. These are not likely to meet with the approval of engineers, who might be ready to use a substantial instrument which would stand as much knocking about and give as accurate readings as a four-inch theodolite. A galvanometer cannot be fairly compared with a theodolite, since not only the pendulum action but the "liveness" of the moving part are altogether different from the stiff-clamped vernier of the surveying instrument. But in instruments which are free from the pendulum difficulty, a vernier might easily be applied, by providing a short transparent scale in the eyepiece. A four-inch theodolite reads to one minute of arc, which is equivalent to 0·58 of a "Central Institution scale division." In recommending the attention of instrument makers to microscope methods of reading, we would only add that the theodolite was developed by engineers, and has arrived at its present form by the modifications suggested by engineers, and it is essentially an engineer's instrument.

REVIEWS.

Dynamo-electric Machinery. By SILVANUS P. THOMPSON. Fourth edition, enlarged and revised. (London: E. and F. N. Spon. 1892.)

The fourth edition of a standard work does not generally require a long review; but the volume before us is of so great value, by reason of the importance of its contents and the rapid development of the subjects with which it deals, that it deserves nearly as much attention as a new book. Since the appearance of the first edition in 1884 no other writer has attempted to compete with it; and the unique position which it holds as the only comprehensive treatise on dynamo-electric machinery increases the responsibility of the author in providing electrical engineers with a complete and trustworthy text-book. In the attempt to discharge this responsibility the whole work has been revised, very little omitted, and much, including new chapters on alternating motors, the theory of armature winding, dynamo design, transmission of power, and the management of dynamos, has been added, together with a number of folding plates giving scale drawings of various machines. The volume, as a result, is of an unwieldy size, and of such a thickness that nothing but the very strongest binding will hold it together. Including as it does the history, theory, practical design, and description of examples, two if not three volumes might have been made, two being works of reference, and one for workshop or office use.

The historical chapter is so short that it need only be mentioned to commend it for its brevity. In the earlier editions a great deal of space was occupied with descriptions and illustrations of experimental, unsuccessful, and obsolete machines. Copious references to fuller accounts of these early forms are given in footnotes, and many of these refer to patent specifications. We notice that the account of Isenbeck's research on the action of the Gramme ring, together with the author's experiments on the effect of pole-pieces, have been omitted in the new edition. These experiments were of considerable interest, but the conclusions drawn from them were open to question. The diagrams of different modes of connecting field-magnet circuits, which have been copied into dozens of books, including even pocket-books, have been re-engraved with modernised outline, the change recalling the modification of the Edison dynamo by Hopkinson. The chapter on armature reaction brings together some very valuable information, but we find no warning of the troubles of large dynamos, especially of two-pole ring armatures. It is impossible to build these above a certain size. A note on this point might be added at the end of Chapter V., in which the theoretical relation of output to efficiency is discussed. The act of commutation of a section of an armature is clearly shown in a diagram, and some useful hints are given about sparking. It is evident, says the author, that sparklessness will be promoted by, amongst other methods, so shaping the pole surfaces as to give a suitable fringe of magnetic field of graduated intensity. More definite information on this point, if it could be given, would be useful to more than one firm of dynamo builders, who have had immense trouble with multipole machines, and who have only cured their sparking by paring away the pole-pieces. An excellent diagram is given showing the generation of eddy currents in core discs; but further information might be given as to the degree of lamination necessary in different cases. A general rule is given (p. 98) that they should not exceed 2 millimetres, and on p. 342, in a chapter on the practical construction of armatures, it is stated that the usual thickness is from 1 to 2mm. In the chapter on examples of modern dynamos, only one instance of the thicker limit is given, in the Mather and Platt dynamo described on pp. 412 and 520, where about 1,000 plates went to an armature of a gross length of 50·8cm. The Brown dynamos, described on p. 490, have discs of a thickness of 20 B.W.G. (rather less than 1mm.), and in the Phœnix dynamo, described on p. 417, the same thickness is used. In the other machines no data on this point are given. Some information on the effect of thickness of the discs on hysteresis and eddy-current losses might have been given with advantage in connection with the Kapp and Housmann method of testing such losses on p. 792. The Thomson law of economy might be applied in this case; but practically we believe that No. 20 gauge should not be exceeded, and some makers use thinner plates. A word of warning might have been introduced against the use of mild steel both for armature discs and for field magnets in general cases, in the admirable chapter on magnetic principles.

The following chapter (VII.), on the magnetic circuit, seems to be rather needlessly mathematical. If the book could be divided into theoretical and practical sections, or volumes, much of this would have to be classed in the former category, while the worked-out examples might be given in connection with rather more definitely expressed rules in the workshop volume. To the collection of forms of field magnets, which has been an interesting feature of former editions, several additional types are given; but the supposed advantages of the iron-clad fields are not discussed, nor is the real necessity for the use of more than two poles for large dynamos mentioned. The elementary theory of the dynamo is of little use to the manufacturer, and much of it really belongs to the Rankine order of engineering literature. The calculation of the fluctuations due to the number of commutator bars and setting of the brushes was worth investigating in the first instance, but is hardly of sufficient importance in general work to warrant its reappearance in the present edition. The theory of self-

Digitized by Google

regulation is treated in a Rankine fashion, and the excellent practical rules for compounding are rather buried between mathematical formulæ and a diagram of characteristics of very old-fashioned compound-wound machines.

The new chapter (XII.) on the winding of armatures and the theory of connections is a most elaborate and remarkable study, and the first five diagrams of ring and drum winding are the perfection of clearness. The developed diagrams of winding which are given side by side with the circular diagrams are a most important addition, and not only render the examination of any peculiar mode of winding very much more easy, but should be of great value for drawing office and workshop use. Winding tables, or directions to the armature winder, are a little difficult to follow; but each engineer and indeed many winders have their own ideas on this subject, and the introduction of a new system, however perfect, might lead to serious trouble. Each maker, too, sticks as a rule to one mode of winding; and while the diversity of windings and the great complication of some of them speak highly of the immense pains which the author has taken in collecting and clearly illustrating them, the student, and the mechanical engineer who studies this book for the purpose of learning how to build dynamos, need not be staggered and disheartened at the intricacy of these pages. The next chapter, on the practical construction of armatures, is a welcome return to engineering. The most common way of mounting and driving the core, described as the Kapp mode of driving, is shown only in transverse section; a modification,—Brown's system is shown in perspective. Carbon brushes are said to be used now frequently, both for dynamos and motors, but it is singular that a special search at the Crystal Palace Exhibition revealed only one example. Bedplates are dismissed at the close of a chapter on mechanical points in design and construction, without reference to the important method introduced in connection with the Willans engine, at first to meet the stringent requirements of the Admiralty as to space and weight, but now commonly adopted in central-station work. A short account of the results of the committee of the Institution of Mechanical Engineers on friction and lubrication would be a valuable addition to this chapter.

The chapter (XVI.) on the elements of dynamo design is rather unequal. It contains a good deal of very valuable teaching, but much of it must be reduced to plain rules of a more or less empirical kind to make it fit for drawing-office work. Twice in this chapter it is remarked that modern practice allows from 2,000 to 3,000 amperes per square inch in armature conductors. The proper rules, based on the emissive surface, are given further on; and a useful table is given in an appendix, where this unscientific rule is again repeated in the immediate context of the correct one. It would be only fair to the student to tell him that dynamos are not designed in the manner described in this chapter in everyday work. After a few years' experience each manufacturer has an accumulation of records of tests and experiments on a series of machines of different sizes from which, with but little labour and trifling calculation, he can build any intermediate or modified machine with a much greater certainty of a specified output than can be relied upon by a steam-engine builder. Much of the calculation here given underlies the design of dynamos, just as thermodynamic considerations underlie steam-engine work. In striking out an altogether new departure these formulæ may be useful to those engineers who can thoroughly master them; but these are, and in all probability will be few, until engineering has made an enormous change.

The principles of alternate-current work are discussed very concisely, and the description of the best known types of dynamos confirms us in our opinion that these are in their infancy compared with continuous-current machines. A short chapter is devoted to transformers and their complicated mathematical theory which has attracted so undue a proportion of attention. The electric transmission of energy, regulators for dynamos, the testing and management of dynamos and motors bring this important and we may say indispensable book to a close. The arrangement of the contents is a great improvement upon that of former editions, and a descriptive heading is given to the alternate pages, as indeed should always be done.

DYNAMO BRUSHES.

An excellent opportunity is undoubtedly afforded by the Crystal Palace Exhibition for comparing the practice of various makers with regard to the details of dynamo design; indeed, it is extremely unlikely that so comprehensive a collection of machines will be shown again in this country for some time. We have taken the opportunity, therefore, of examining the kinds of brushes most in use at the Exhibition. For machines carrying heavy loads, wire gauze brushes seem to be preferred, brushes of this description also being adopted on machines exhibited by the Electric Construction Corporation, Messrs. Easton and Anderson, Johnson and Phillips, H. F. Joel and Co., Kent and Sharp, Cathcart, Peto, and Radford, Wilson Hartnell, Laurence, Scott and Co., the Roper Engineering Company, and the Newton Electrical Engineering Works. Copper wire brushes are in use on all Messrs. Siemens' machines, both alternating and continuous current, as well as on the Thomson-Houston alternator, a Thomson-Houston continuous-current dynamo having brushes of sheet copper terminating in a number of tongues or divided narrow strips. Ordinary sheet metal brushes are employed on most of the Laing, Wharton and Down machines, on those of Messrs. Crompton and Co., Messrs. Dorman and Smith, and Messrs. Appleton and Burbey.

In one case only could we discover an example of the adoption of carbon brushes. In a motor made by a French firm, Messrs. Piat and Co., for working an electric rivetter, we understand that four brushes are employed, two being of gauze and two of copper-plated carbon. We hear that carbon brushes are used in connection with the Davis and Stokes closed commutator for mining motors. American electric traction engineers say that carbon brushes are the greatest boon to them, and yet not a single one is visible at the Crystal Palace. Many experiments have been made with carbon brushes, and the theory of their action is fairly clear. They were first employed, we believe, on Prof. Forbes' uni-polar or non-polar dynamo, where they were used only as collectors, and their real advantage in smoothly short-circuiting commutator sections was not made use of at all. The difficulty appears to be, that they will not take anything like the current that is carried by a metallic brush.

THE USE OF WATER-POWER FOR ELECTRICAL PURPOSES.

BY NORMAN F. WILSON.

(*Continued from page 169.*)

Outward-Flow Turbines.

A very large number of this type of turbine are used on the Continent, on both high and low falls, for all kinds of work. That the efficiency of the wheel is in no way reduced when the diameter is increased is a great point in favour of the Girard, and others of the outward-flow type of turbine. This is especially important when the fall is very high and the speed of the periphery of the wheel is great in consequence, since by increasing the wheel in diameter the turbine shaft can be made to revolve at any given number of turns per minute. As an inward-flow turbine has always to be kept full of water if it is to work at its best efficiency, the size of the wheel is to a great extent dependent on the quantity of water which has to pass through it; a wheel cannot be indefinitely increased in diameter without causing a considerable loss in efficiency when the water is passing through it. Therefore, if the quantity be small, as is frequently the case when the fall is high, the wheel must be small in diameter, and the speed of the shaft becomes inconveniently high. The water acts on an outward-flow turbine by impact only, and need not be supplied to all the wheel at once it is quite sufficient if five or four, or even a single bucket at a time, be kept supplied. Moreover, when the water is passing through the vanes of the wheel it does not entirely fill them, so that the limitations in size which affect inward-flow turbines (and all others which are capable of working by suction) are entirely dispensed with, and the diameter of the

Digitized by Google

wheel may be increased at pleasure. Outward-flow turbines are not so quite so efficient as inward-flow, are more liable to race, and are adversely affected by backwater when the level of the tailrace rises; but with a partial supply of water they give a much better efficiency than many turbines of other types.

Figs. 5 and 6 illustrate the general construction of a vertical outward-flow turbine for medium and high falls. The water entering through the mouth A, is directed by the guides C C on to the shaft F. The water does not entirely fill the buckets. The small holes G are for allowing the atmospheric pressure to reach the water freely; if these were not provided the water would tend to form a vacuum in the empty part of the vane which would retard its exit from the wheel.

Outward-flow turbines are most frequently placed horizontally with a vertical shaft, as by this arrangement very little fall is lost in allowing the water to leave the wheel freely; but

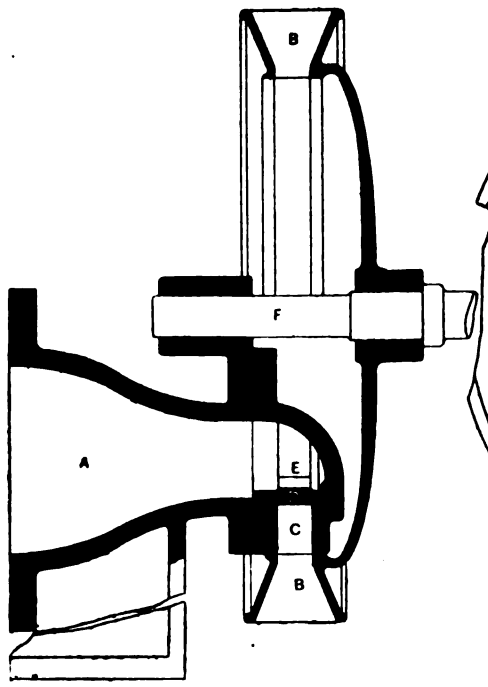

FIG. 5.—Vertical Outward-flow Turbine. Sectional Elevation.

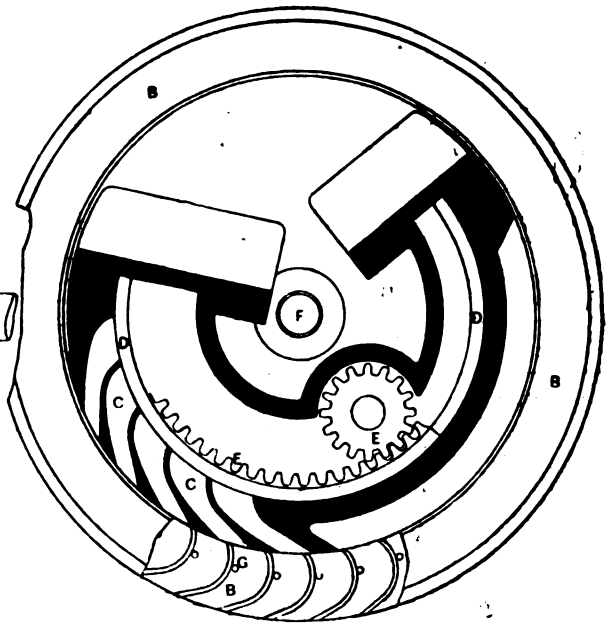

FIG. 6.—Vertical Outward-flow Turbine. Sectional Plan.

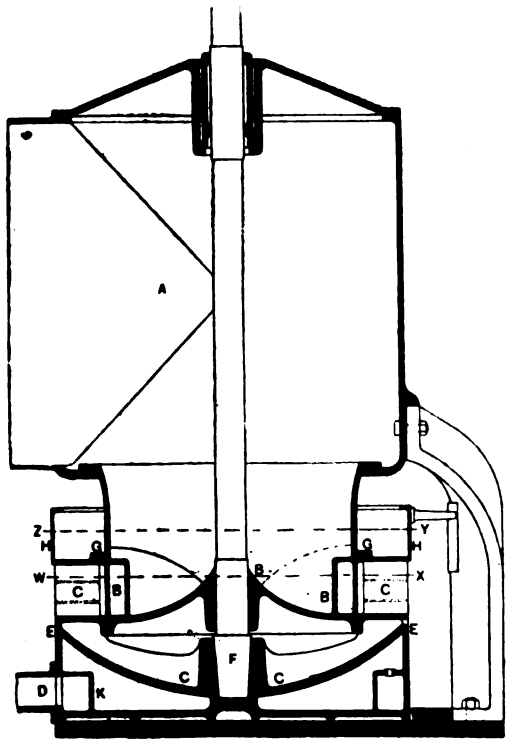

FIG. 7.—Fourneyron Outward-flow Turbine. Sectional Elevation.

when the fall is high and a foot or so can be sacrificed, they may be arranged with a horizontal shaft without detriment.

Figs. 7 and 8 show the elevation and plan of M. Fourneyron's outward-flow turbine. The water enters through the pipe A, and is directed by the guides B B against the vanes of the wheel C. The top of the guide blades are covered over at the

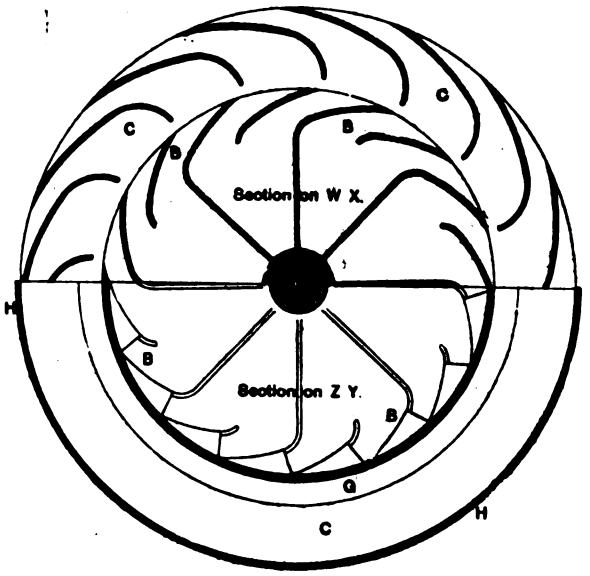

FIG. 8.—Fourneyron Outward-flow Turbine. Sectional Plan.

against the vanes of the wheel B. When the supply of water falls short, or it is desired to stop the motor, one or more of these passages, C C, can be closed by the brass slide D, which is moved backward or forward by the rack and pinion wheel E. In the figure all the guide passages are shown closed. The wheel B is generally made of brass or cast iron, and is keyed

point in order to control the direction of the water more efficiently. The metal strip G forms a water joint between the revolving wheel and the guide-blade chamber. H is a circular sluice for stopping the turbine. In order to avoid being obliged to support the weight of the wheel, shaft, and gearing on a wooden pivot, a small pipe, D, is taken from the supply pipe

Digitized by Google

to the circular chamber K beneath the wheel. The whole of the under surface of the wheel C is thus subjected to the full pressure due to the head; this pressure, acting over so large a surface, is amply sufficient to carry the weight of the wheel, &c., and raises it a small fraction of an inch above the stationary casing E. The wheel then revolves on the thin film of water escaping between the casing E and itself. This arrangement (with modifications, *see* Fig. 10) can be adopted with very many turbines, which are placed at the bottom of the fall, and dispenses with the pivot or suspension bearing on the upright shaft. It is found to work well in practice, and the extra initial cost is not large.

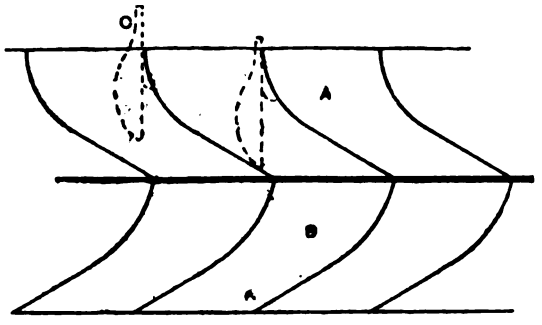

FIG. 9.—Axial-flow Turbine. Form of guide passages and vanes.

The turbine illustrated in Figs. 7 and 8 is not provided with any efficient apparatus for working with a partial supply of water. When it is desired to work a turbine of this class with only two-thirds, half, or a quarter of the full supply, the wheel is divided into two or more horizontal sections (as shown by the dotted lines in Fig. 7), and a circular regulating sluice is placed between the wheel and the guides; this sluice may be raised to admit the water into one or more divisions of the wheel, according to the power required. The disadvantage of

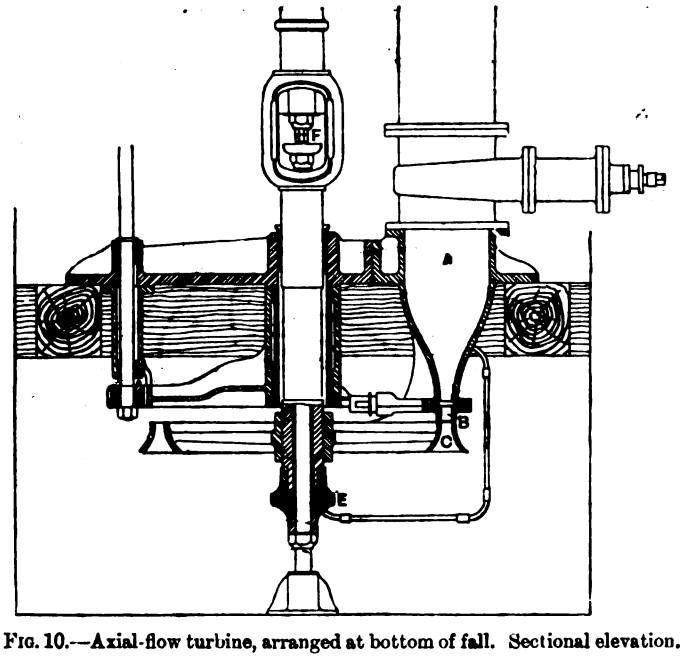

FIG. 10.—Axial-flow turbine, arranged at bottom of fall. Sectional elevation.

this method of regulation is that only two or three definite proportions of the power can be efficiently obtained; with intermediate powers it is not so satisfactory. A wheel divided in this manner becomes virtually two or three separate turbines.

Axial-Flow Turbines.

The axial-flow turbine is so called because the water approaches and leaves the wheel in a direction parallel with the shaft, which is generally vertical. M. Jonval, it is believed, was the first to bring this type of turbine into practical use; he was ably seconded in his efforts by M. Girard and other hydraulic engineers, and now these turbines are used and manufactured all over the world. This turbine gives a good efficiency, and runs more steadily under a varying load, than the outward-flow. It also possesses one advantage claimed for inward-flow turbines, in the fact that the wheel may be placed above the tail water level and part of the fall be utilised by suction. Fig. 9 shows the form of the guide passages and wheel vane of an axial-flow turbine; the stationary guide-blade chamber A being fixed above the revolving wheel B.

These turbines may either have the water admitted to them all round the wheel, or only to a few buckets at once, as in an outward-flow wheel. When the wheels have only partial admission the diameter of the wheel may be varied at pleasure without affecting the efficiency, and there is no difficulty in regulating the power; but in this case it cannot work by suction, and is hampered if the water rise in the tail race. When the water is supplied to all the buckets at once the diameter of the wheel cannot be increased so much, and the power cannot easily be varied, but the turbine may then be fixed so as to utilise part of the fall by suction, which is often a convenience. When the turbine is fixed in the latter position the best way to adapt the wheel for varying supplies is to divide it into concentric rings, the divisions running parallel to the shaft instead of being at right angles to it, as in Fig. 7. This method gives fairly good results, but adds considerably to the cost of construction. When these turbines are placed at the bottom of the fall (Fig. 10) there are many ways by which the guide passages may be reduced in area when the supply runs short. Some of these arrangements are not very practical, as their working is liable to be obstructed by sand and *debris*.

The method of partially closing the guide passages by vertical slides (Fig. 9), although in common use, is not to be recommended. In the first place, the slide often cannot be shut down without difficulty; and, secondly, the placing of a somewhat abrupt obstacle in the way of the water retards the velocity of its flow, and thereby reduces its working power. It is much better to entirely close a number of the passages either by flaps, which may be lowered over the posts, or by a slide, as is done in the turbine illustrated in Fig. 10, which shows how an axial-flow turbine is arranged at the bottom of the fall. The water comes down the pipe A on to the top of the guide blades B, and is directed by them on to the wheel C. The slide for opening and closing the guide passages is worked by the sector and pinion D. The wheel is keyed on to a hollow cast-iron shaft, whose weight is partly supported by the water-bearing E, and partly by the suspension-bearing F.

(To be concluded.)

THE MANAGEMENT OF BOILERS.*

Safety.

Overloading or neglect may lead to disastrous results. Safety valves should therefore be tried at least once every day to see that they act freely.

The pressure gauge should stand at zero when the pressure is off, and it should show the same pressure as the safety valve when that is blowing off. If not, one is wrong. Compare gauge with correct one.

Before starting see that the water is at the proper height. Do not rely on glass gauges, floats, or water alarms, but try the gauge cocks. If they do not agree with water gauge, learn the cause and correct it.

Gauge cocks and water gauges must be kept clean. Water gauges should be blown out frequently, and the glasses and passages to gauge kept clean. The Manchester Steam Users' Association attribute more accidents to inattention to water gauges than to all other causes put together.

The feed pump or injector should be kept in perfect order, and be of ample size. No make of pump can be expected to be continuously reliable without regular and careful attention. Have two means of feeding a boiler. Check valves and self-acting feed-valves should be frequently examined and cleaned. See that the valve is acting when the feed-pump is at work.

* All rights reserved. From a forthcoming work by Messrs. Geipel and Kilgour (*The Electrician* Printing and Publishing Company).

Digitized by Google

In case of low water, immediately cover the fire with ashes (wet if possible) or any earth that may be at hand. If nothing else is handy use fresh coal. Draw fire as soon as it can be done without increasing the heat. Neither turn on the feed, start or stop engine, or lift safety valve until fires are out and the boiler cooled down.

Blisters and cracks are liable to occur in the best plate iron. When the first indication appears there must be no delay in having it carefully examined and properly attended to.

Fusible plugs, when used, must be examined when the boiler is cleaned, and carefully scraped clean on both the water and fire sides.

Economy.

Fire evenly and regularly, a little at a time. Moderately thick fires are most economical, but thin firing must be used when the draught is poor. Take care to keep grates evenly covered, and allow no air holes in the fire. Do not "clean" fires oftener than necessary. With bituminous coal, a "coking fire," *i.e.*, firing in front, and shoving back when coked, gives best results if properly managed.

All heating surfaces must be kept clean, outside and in, or there will be a serious waste of fuel. The frequency of cleaning will depend on the nature of fuel and water. As a rule, never allow over $\frac{1}{16}$in. scale or soot to collect on surfaces between cleanings. Hand-holes should be frequently removed and surfaces examined, particularly in case of a new boiler, until proper intervals have been established by experience. Examine mud-drum, if any, and remove the sediment therefrom. In using smoking fuel, it is best to occasionally brush the surfaces when steam is off.

Cold water should never be fed into any boiler when it can be avoided, but when necessary it should be caused to mix with the heated water before coming in contact with any portion of the boiler.

When foaming occurs in a boiler, checking the out-flow of steam will usually stop it. If caused by dirty water, blowing down and pumping up will generally cure it. In cases of violent foaming, check the draught and fires. If found to prime, lower the water-line.

Be sure that all openings for admission of air to boilers or flues, except through the fire, are carefully stopped. This is frequently an unsuspected cause of serious waste.

If feed-water is muddy or salt, blow off a portion frequently, according to condition of water. Empty the boiler every week or two, and fill up afresh. When surface scum-cocks are used, they should be often opened for a few minutes at a time. Make sure no water is escaping from the blow-off cock when it is supposed to be closed. Blow-off cocks and check-valves should be examined every time the boiler is cleaned.

Durability.

When leaks are discovered, they should be repaired as soon as possible. Never empty the boiler while the brickwork is hot.

Never pump cold water into a hot boiler. Many times leaks, and in shell boilers serious weaknesses and sometimes explosions, are the result of such an action.

Take care that no water comes in contact with the exterior of the boiler from any cause, as it tends to corrode and weaken the boiler. Beware of all dampness in seatings or coverings.

Examine frequently parts in contact with copper or brass, where water is present, for signs of corrosion. If water is salt or acid, some metallic zinc placed in the boiler will usually prevent corrosion, but it will need attention and renewal from time to time.

In boilers with thick plates or seams exposed to the fire, steam should be raised slowly, and rapid or intense firing avoided. With thin water tubes and adequate water circulation, no damage can come from that cause.

If a boiler is not required for some time, empty and dry it thoroughly. If this is impracticable, fill it quite full of water, and put in a quantity of common washing soda. External parts exposed to dampness should receive a coating of linseed oil.

All things about the boiler-room should be kept clean and in good order. Negligence tends to waste and decay.

Boiler Inspection.

The boiler should be examined externally for corrosion and leaks. All internal seams should be examined and effects of corrosion and pitting noted. Stays should be seen and tested by a hammer to ascertain if they are cracked or broken. After thorough examination test hydraulically with water at 180° to 210°F. to a pressure 50 per cent. greater than working pressure, the boiler having had time to become of uniform temperature throughout. While under pressure try flat surfaces with a straight-edge, and note any change of form, and test all external surfaces with light blows of a hammer. When pressure is off, permanent set or alteration of shape should be noted.

Fire-box stays or other stud stays may be drilled with an $\frac{1}{8}$in. hole deep enough to reach the water-space, and if leakage takes place renew the stay.

If set in brickwork, that which is in contact with the plates should be removed as far as possible. Man-hole and mud-hole covers, fire bars and bridge should be removed, and every part of boiler should be cleaned to facilitate inspection.

New boilers should be inspected every year, old ones every six months.

ELECTRIC SUPPLY AT OXFORD.

After the cramped and dark engine-rooms of most London stations, the generating station at Osney, on the outskirts of Oxford, is so light and airy as to remind one of a conservatory. The ample space in the engine-house, as well as the boiler-house, is, of course, partly due to the fact that only three sets of plant have as yet been laid down; there is room for another, making half the full complement, which will be added when required. Being free from the harassing restrictions of the Metropolitan Building Act, the side of the engine-room on which the future extension will be made is filled in with corrugated iron. The generating station is close to the Great Western Railway Station, and is situated on the bank of a branch of the upper river, from which condensing water, which is also well adapted for steaming, can be drawn. Three vertical triple-expansion engines by M'Laren, of Leeds, run at 120 revolutions per minute, and drive Elwell-Parker continuous-current dynamos by belts. The engines are surface-condensing, with the air pump at the back, and give 120 B.H.P. Fly-wheel governors are used to shift the eccentric of the high-pressure cylinder. Three multitubular locomotive boilers, also by M'Laren, supply steam through a ring main at 140lb, but it is intended at times of full load to use 160lb. if necessary. There is room for three more boilers of the same size. A Green's economiser is provided, and the result of the maker's steam trials was very satisfactory. Three smaller dynamos, driven by ropes from the shaft of the generating machines, are used as exciters, or for charging a small local accumulator of 53 11-L. E.P.S. cells. The generating dynamos are drum wound, with fine stranded conductors; the ends are not provided with strip end connections. The output of each is 80 amperes, at 1,050 volts, or 84 units, at 400 revolutions per minute. The switchboard at this station is remarkably simple. The left-hand part is provided with double-pole switches on omnibus bars, to which the generators are coupled in parallel. Two pairs of Silvertown cables, drawn into iron pipes, take the high-pressure supply into the town, where a central switch-station is provided in Broad-street. Ammeters, showing the current generated by each dynamo and by each exciter, are provided on the right hand, and a sliding resistance switch controls the shunts of the exciters. No regulation of pressure is attempted at present at the generating station, but a steady reading of 1,050 volts is maintained on a Thomson electrostatic voltmeter; but there seems to be no reason why a rather lower pressure could not be used during the day.

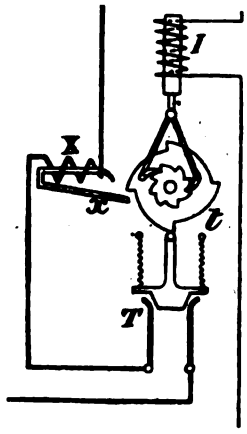
There are three sub-stations in Oxford, one at the switch station in Broad-street, one in King-street, and one in Queen-street, Carfax. At Broad-street a battery of 140 31-L accumulators of E.P.S. make are provided, together with a dynamotor or continuous-current transformer, similar to that shown at the

Digitized by Google

Crystal Palace Exhibition, and illustrated in *The Electrician*, Vol. XXVIII., p. 424. Dynamotors of the same size are placed in the other two stations, in which there is room for two more. The output of these machines is 360 amperes at 108 volts, and they are driven by a current of 40 amperes at 1,000 volts. They run at 500 revolutions per minute, and are continuously lubricated by circulating oil pumps.

The method of regulation and use of these dynamotors is fully described in the patents of Parker, Woodward and Rees, Nos. 16,110 (1890), 13,942 (1891), and 18,348 (1891). It is under the control of one man at the central switch station, where voltmeters are provided showing the pressure on the network from which the consumers take their supply at 105 volts. When, owing to the draught upon the mains, the pressure begins to fall, and it is necessary to feed the network by one of the dynamotors, the man in charge of the switch station closes a double pole switch, which starts the continuous-current transformer as a series motor, the fields being feebly magnetised by a few turns of series winding carrying the high-pressure current. A circular resistance switch is provided, by which a considerable resistance is put in circuit at first, and is gradually altered as the armature gets up speed. When it begins to run, it excites its own shunt coils; and although, as a series motor running free, it would acquire a dangerous speed if the current were not held in check by the resistance, the shunt field soon attains its full strength, and the speed is automatically kept down to the normal 500 revolutions per minute, although the machine is running idle.

In order to put the generating circuit on to the supply network, an ingenious magnetic switch is used. A small switch at



the switch station is momentarily closed, and this short circuits the pilot voltmeter and allows a few amperes to pass through a large ironclad solenoid coil, which is always in the voltmeter circuit. This is represented diagrammatically in the figure by I, the thin lines representing the pilot wires. The core and iron disc which form the armature of the solenoid carry two pawls, which engage with a ratchet wheel. With the up stroke of the armature one pawl pulls a tooth, and with the down stroke the other pawl pushes a tooth. This movement of the ratchet wheel brings a cam *t* to bear on a large double switch, T and thus connects the transformer to the supply mains. The circular resistance switch which was used for controlling the starting current, can be pushed over beyond the zero point, to put coils of small resistance, but capable of carrying the whole current, into circuit, to control the voltage. An automatic cut-out carrying the whole low-pressure current is provided. This is represented by X in the diagram. In the event of heavy short-circuit the armature *x* is lifted, and this, striking a tooth of the cam wheel, breaks the connection between the dynamotor and the supply network. When the load has fallen to such a point that the feeding of the supply mains by any one secondary generator is no longer necessary, the attendant closes and opens the short-circuit switch, causing the ratchet wheel to move round; and the cam, passing forward, releases the main switch. Before thus breaking the circuit, the dynamotor is slowed down by introducing a resistance in the high-pressure circuit until the speed drops to such a point that the ammeter shows that no current is passing into the mains. The switch can then be opened without sparking. The brushes on the dynamotors give no trouble, and do not require to be shifted, as the reactions of the two windings neutralise each other.

In the daytime, one of the dynamotors is used to charge the batteries at Broad-street, and these take up the load after midnight. The supply is being taken up in an encouraging manner, and five 15-ampere Brockie-Pell arc lamps are being tried for street lighting. The low-pressure network consists of Callender cables armoured with steel tape. The progress of this station will be watched with great interest, as an important example of sub-station supply with continuous currents. Although the working of the magnetic switch cannot be described in a few words, it is not a complicated piece of apparatus, and it is most substantially made. The work seems to have been carried out very carefully and methodically, and everything looks favourable to successful operation.

TEST OF TWO 6,500-WATT WESTINGHOUSE TRANSFORMERS.*

Before giving any of the results of the tests I have made with your transformers it will be well to explain the methods of experiment adopted. The instantaneous value at any epoch in the period of the difference of potential between any two points of a circuit in which the potential difference is varied periodically is made effective on the measuring instrument by means of a rotating contact-maker attached to the shaft of the alternate-current generator. This contact-maker was constructed for the King's College laboratory by Messrs. Siemens Brothers. It makes contact once in each revolution for a period of about three-quarters of a degree, and breaks it for the rest of the revolution. It is entirely insulated, and so can be

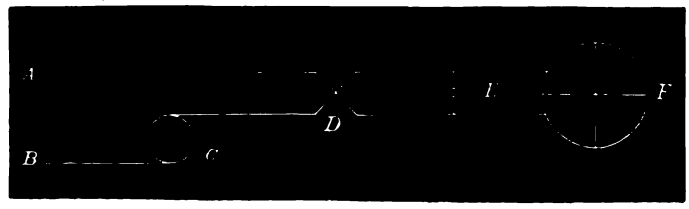


FIG. 1.

connected to any part of any circuit. The position of the contact can be varied, and the variations be read off on a graduated circle of 13½in. diameter divided into degrees, and by estimation the variation can be read to one-tenth of a degree. The two points between which it is desired to measure a potential difference are connected through the contact-maker to a condenser and a quadrant electrometer as shown in Fig. 1, in which A and B are the points, the potential difference of which at a stated epoch is to be measured, C the revolving contact-maker, D the reversing switch of the electrometer, E the condenser of which the capacity can be varied, F the quadrant electrometer. It is evident that the quadrant electrometer will give a reading proportional to the potential difference of A and B, when C makes contact. If there were no leakage it would at once give this potential. It is to obviate the effect of leakage that the condenser is introduced, and the amount of the effect was determined by varying the condenser, thus:—When the condenser had capacity 1, 0·5 and 0·2 microfarads the readings of the electrometer for a given potential difference of an alternating current at the position in the period of maximum electromotive force were 138, 136, and 132 respectively. The rate of loss of potential will be proportional to the reciprocal of the capacity, whence we at once infer that the true reading, if insulation were perfect, would be 139½, and hence the readings are always corrected by adding 1 per cent. When the potential difference was too great for the electrometer it was reduced in any desired ratio by two considerable resistances introduced between the points

* A report made by Dr. John Hopkinson to the Westinghouse Electric Company.

Digitized by Google

to be measured in the usual way, thus (Fig. 2). The potential difference may, of course, be measured in other ways. An ordinary voltmeter may be placed between A and B, in which case it must be standardised with the contact-breaker in circuit; and it will depend for its constant on the duration of the contact, which may vary. Further, it gives, not the difference of potential at any definite epoch, but the mean difference for the whole time of the contact. The condenser may be used and its potential be measured by discharge through

Fig. 2.

a galvanometer; this is open to the objection that if there be any leakage the result will depend on the time at which the contact is broken by the condenser key in relation to the time at which it was made by the revolving contact-maker. Lastly, a Clark cell may be used, by a method which Major Cardew pointed out to me, thus (Fig. 3), the resistance being adjusted till there is no deflection. This is open to the same objection as the first, namely, that it gives the mean of the potential differences which occur during the contact. By making use of the first-mentioned method, we have the means of measuring accurately any potential difference at any epoch of the period, and of knowing the epoch.

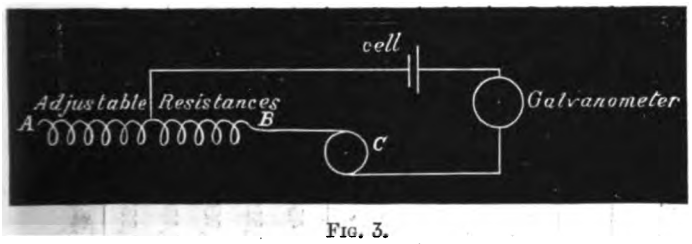

Fig. 3.

For these experiments, two transformers intended to be identical were available, each transforming between 2,400 and 100 volts. It was most convenient on account of the resistance available to couple these transformers up from 100 to 2,400 in the first or No. 1 transformer, then down from 2,400 to 100 in the second or No. 2 transformer, and to take up the energy from the second in a non-inductive resistance. The arrangement is thus (Fig. 4).

The obvious way of determining the efficiency of the combination would be to measure, at various epochs of a half period, the potential differences of the terminals of the machine and

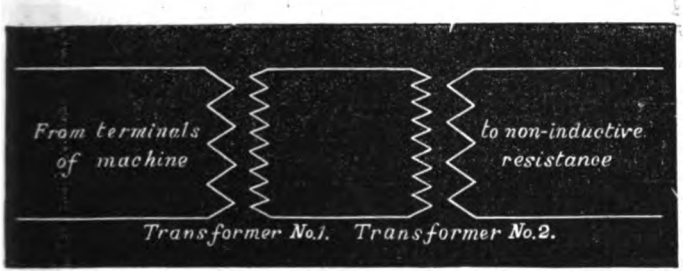

Fig. 4.

the current passing in the No. 1 transformer; in like manner, at the same epochs, to measure either the potential differences or the current passing to the non-inductive resistance, thence to deduce the power supplied to the first transformer and taken from the second. This would be open to certain objections; we are comparing two nearly equal magnitudes and desire their ratio, the ratio will be afflicted with the full error arising from an error in the determination of either magnitude; and such errors may be material, as the observations are not simultaneous, and conditions may change between one series of observations and another. These objections are avoided by the method adopted. The current from No. 2 is observed at certain epochs, the difference of current between No. 2 and No. 1, and the difference of potential difference of No. 2 and No. 1, at the same epoch. These give the currents and potentials of No. 1 at the same epochs as the corresponding determinations of No. 2, and the difference will only be afflicted with the

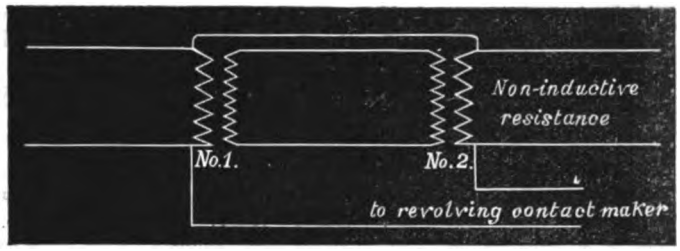

Fig. 5.

proportion of error of those differences. For example, suppose the efficiency of the combination were 90 per cent., and the possible error of determination of power 1 per cent., our result might be anything from 38 per cent. to 92 per cent. if made in the obvious way, but if made by differences the maximum loss would be 10·1 per cent., and the possible least determination of the efficiency would be 89·8 per cent. The method is essentially similar to the method I described* and subsequently used for testing dynamos. The measurements for difference of potential differences are made as in Fig. 5. For current difference (Fig. 6), where G is a known small non-inductive resistance, the two currents will, of course, slightly disturb each other; but this is readily allowed for in the calculations.

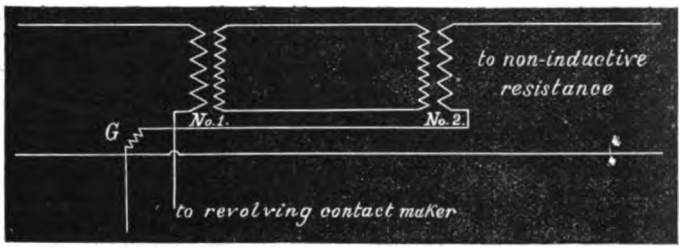

Fig. 6.

Another method would be to couple them thus (Fig. 7), G_1 and G_2 being equal non-inductive resistances. This arrangement is quite free from disturbance, but requires two resistances adjusted to exact equality. A single transformer can be tested in the same way, though, in this case, reliance must be placed upon resistances to reduce the current of the low

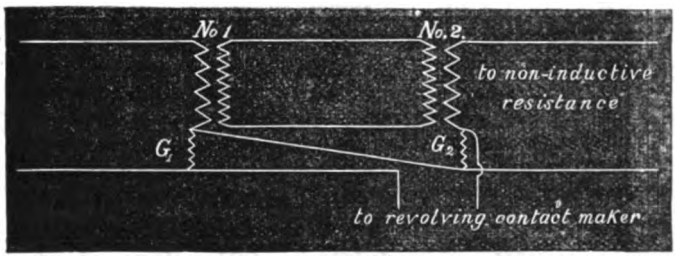

Fig. 7.

potential coil, and to reduce the potential of the high potential coil in the ratio of the number of windings in the two coils.

The current was throughout generated by a Siemens alternator with 12 magnets, run at a speed between 830 and 840 revolutions per minute, which gives a frequency of 5,000 per minute, or 83 to 84 per second.

The first experiment tried* was with the two transformers coupled; but with No. 2 transformer on open circuit, or on nearly open circuit, for a high resistance for purposes of measurement was interposed between the terminals of the low-resistance coil of No. 2 transformer. The actual results are given in Table I., and are expressed in Curve I. Tables II., III., and IV., give the results for half-power, nearly full power, and full power, and the sets of curves of corresponding numbers give the results of the tables. In these tables the first column gives the position of the contact brush in degrees, so that 60 on this scale corresponds with a complete cycle. Three degrees are thus $\frac{1}{83{\cdot}3 \times 20}$ of a second. The second column of No. I. Table is the current in the thick coil of No. 1 transformer, as determined by the difference of potential at the two ends of a non-inductive resistance in which the current

Curve IV.

* So far as I know, the first discussion of endless magnetic circuit transformers, based on the actual properties of the material, is in a note by myself (*Proc. Roy. Soc.*, Vol. XLII., and *Electrician*, Vol. XVIII., p. 421). Definite results were obtained by methods generally similar to those now used by Prof. Ryan (*Electrician*, January 10 and 17, 1890). The theory of transformers is well set forth by Prof. Fleming (*Electrician*, April, 22 and 29, 1892).

passes. The third column is the potential difference of No. 2 transformer, a direct determination. The fourth column is solely for the purpose of determining the square root of the mean of the squares of the third column. This column is a direct determination of the difference of potential of No. 1 and No. 2 obtained in the manner explained with reference to Fig. 5.

The sixth column, is the deduced potential difference of the terminals of the thick wire of No. 1 transformer, being the sum of the third and fifth column. The seventh column, like the fourth, is merely for the purpose of determining the square root of the mean of the squares of column six, whilst the eighth gives the rate at which power is given out by or received by the pair of transformers.

(To be concluded.)

A NEW SYSTEM OF ELECTRIC PROPULSION.*

BY H. WARD LEONARD.

In the distribution of electricity from a power station for the operation of electric railways, the only commercial method to-day is by the use of a system of constant E.M.F. operating the motors in multiple arc with each other, and at the present time every consideration of economy and automatic regulation seems to indicate that the constant E M.F. multiple arc system will always be the best for such distributions.

In the use of electric energy by motors operating under conditions of varying speed and torque the best results as regards economy and regulation are obtained when the electric energy utilised has a voltage varying directly as the speed and a current varying directly as the torque ; for it is evident that under these conditions the electric energy required will be always proportional to the power developed.

If we could operate from the constant potential system a shunt-wound motor running at a constant speed and could interpose between this motor and the axle some device equivalent in its effect to an infinite number of different sets of mechanical gears, so that we could make use of any reduction desired, it would enable us while using a constant power to increase the torque as we decreased the speed and *vice versâ*, which is just what is desired in railway practice where the least torque is required when at full speed on the level and the greatest torque is required at the slow speed in starting and in operating on a grade. Numerous and very ingenious devices have been invented for accomplishing this variable mechanical reduction, but on account of the complication, noise and unreliability they have never proved successful.

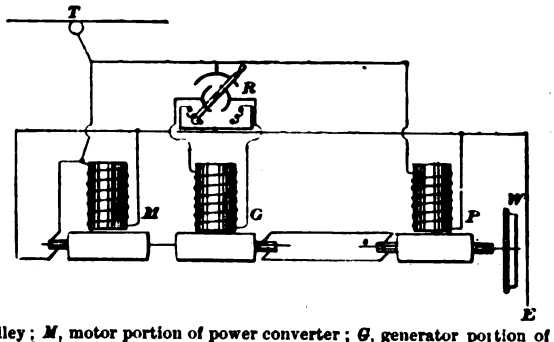
The writer has recently devised an electrical method of securing all the results which could be obtained from such a set of gears described, with a freedom from the noise, wear, complication and rigidity which such a set of gears would necessarily involve.

Following is a general description of the arrangement proposed, indicated by the Figure.

Each axle is driven by a gearless motor, either directly or by means of a connecting rod. The fields of these motors are excited directly from the constant E.M.F. of the line and independently of the armature circuit. Beneath the car and between the axles there is suspended a motor-generator, each armature winding being in a separate field. The motor portion of the motor-generator—which will, for convenience, be called the power converter—is shunt wound and connected just as a shunt motor is for use upon ordinary constant potential circuits. The field of the generator portion of the power converter has its field connected across the line and has inserted in it a regulating and reversing field rheostat. This field circuit is independent of the armature circuit. The generating armature of the power converter is in metallic connection with the armatures of the gearless propelling motors. It will be noticed that this circuit including the armature is a distinct and separate metallic circuit having no connection with the line in any way.

Suppose now that our shunt motor is running at full speed and that our controlling rheostat in the generator field circuit is at its central position, so that the generator field circuit is broken. Although the generator armature is being driven at full speed, it is revolving in a field having no magnetism except the residual magnetism, and hence produces practically no volts. Let us now move our controlling switch so as to place the generator field across the line, but with a resistance in series with the field, of ten times the resistance of the field coils. We now get a slight excitation of the field, and a development of volts at the brushes of perhaps 40 volts. This voltage will produce a current through the armatures of the driving motors dependent upon the ohmic resistance of this circuit only ; and hence, even at this low voltage, a large current will be produced, which, being in a field of full strength, will cause a torque sufficient to start the armature. The speed of the armature will, of course, be governed by the counter E.M.F., which its revolution produces in its strong field ; and hence, just as in the case of a shunt-wound motor, its speed will be practically constant so long as the E.M.F. supplied is constant.

If we now gradually increase the magnetic field of the generator by cutting out resistance by moving the controlling switch, we will gradually raise the E.M.F. of the armature circuit, and with it the speed of the driving motors. Since these armatures are revolving in a constant field, the torque they produce will be exactly proportional to the current in them, and the current will automatically



T, trolley ; *M*, motor portion of power converter ; *G*, generator portion of power converter ; *P*, the propelling motor for the car ; *R*, the regulating and reversing rheostat in field of G ; *E*, the connection to ground ; *W*, the car wheel.

flow exactly as is required to produce the necessary torque to maintain a speed such that the counter E.M.F. will approximately equal the E.M.F. supplied by the power converter. Thus it will be seen that the speed of the car will be dependent upon, and proportional to, the E.M.F. supplied by the power converter ; and the torque or tractive effort will be dependent upon, and proportional to, the current supplied by the power converter.

Let us suppose that 60 amperes flowing through the armatures in fully excited fields will produce a torque sufficient to move the load when upon a grade. It is evident from what we have seen that 40 volts from the power converter will produce this current. Hence, by an expenditure of 2,400 watts in the secondary circuit, or a total power, including field excitation, &c., of about 8 H.P., we can start a fully loaded car upon a grade.

Under the existing systems we would need the same 60 amperes in the same fully excited field, but would necessarily use the full voltage of 500 volts, and therefore consume energy represented by 30,000 watts, as against possibly 6,000 in this system. The current from the line in starting the car under ordinary conditions by this system would be about 12 amperes at 500 volts, instead of from 60 to 100 amperes at 500 volts.

In practice, the controlling switch lever can be instantly thrown from its central position to its extreme position for full speed. The field magnetism of the generator is rapidly increased, and consequently also its E.M.F., which in turn causes a gradual acceleration of the car.

The current in the armature circuit, and consequently the torque, is quite large in the beginning ; but the E.M.F. at this time is quite low, so that the total watts are low ; as the inertia is overcome and the counter E.M.F. begins to approximate to the impressed E.M.F., the current falls off, and finally becomes constant at an amount necessary to produce the torque required to

* Abstract of a Paper read at the General Meeting of the American Institute of Electrical Engineers, Chicago, June 6, 7, and 8, 1892.

Digitized by Google

maintain the speed. The current from the line, and hence the power, gradually increases from zero to the amount required at full speed; but at no time, either at the start or during the acceleration, is the energy from the line greater than that required when we are operating at full speed. It will be noticed that the effect is the same as though we first operated through a set of gear wheels, giving an extremely great reduction of speed and then rapidly changed the ratio of gearing, until finally we operated at full speed with no reduction.

With our hypothetical gears we could, when running at speed, rapidly increase the ratio of gearing, so that the movement of the car would tend to drive the shunt motor faster and faster. This would convert it into a generator forcing current back into the system, which production of electrical energy would act as a brake, and gradually bring the car to rest.

Just so, if, while running at full speed, we suddenly place our switch-lever at its central position the field of the generator will gradually reduce the strength, and the counter E.M.F. of the propelling motors will soon exceed that of the generator. The momentum of the car will now be driving our gearless motors as generators, which will supply current to the former generator, operating it as a motor, causing it to drive the shunt motor coupled to it as a generator, which, in supplying energy to the line, will act as a brake, and smoothly but rapidly bring the car to rest by converting the energy stored up and represented in the movement of the car into electrical energy, which will tend to relieve the work at the central station. Similarly, a car descending a grade, and tending to accelerate in speed, can be made to move at any desired speed without the aid of any mechanical brake, and the energy represented by its falling weight will be converted into electric energy, and the car will become a moving feeder, supplying energy to assist the generators at the central station in the operation of other cars.

It will be evident from what has preceded that with this power converter system we can propel a car upon any practicable grade with a consumption of power no greater than is required to operate the car at full speed upon a level, by merely reducing the speed to the required extent.

In street railways of from five to ten cars, this is of great importance, for it means that we can equip a road with about 6 H.P. per car, as regards the engines and dynamos, and that our conductors can be reduced to about one-third of the amount at present necessary, for we will never require more than 20 amperes at the distant point, where to-day we have to provide for 60 amperes with the same loss and same initial E.M.F.

Under the rheostat system the plant is severely taxed when an unusual crowd must be moved from a certain point, and it is then, when it is of the greatest importance that no break-down should occur, that it usually does occur. With this power converter system we could, upon a five-car road, start up and move with perfect safety 10 or even 20 cars from the most distant point on the road, though of course at a reduced speed, but the crowd would be handled with perfect success, and without subjecting any portion of the plant to any unusual strain.

In the large cities it is no unusual sight to see an electric car moving at the slowest possible speed for perhaps several blocks. Perhaps 12 amperes are required to obtain the necessary torque. This at 500 volts is 6,000 watts. The power required for this slow motion by the proposed system would not exceed one-fifth of this amount.

The cost of car equipment will be increased by the cost of the motor-generator, but as a partial offset to this we have saved the rheostats, two expensive controlling switches and a complex system of wiring. Our motors having constant and fully-excited fields will operate absolutely without spark under all conditions. The control of the car will be entirely accomplished by a small switch and rheostat, handling never more than one half of an ampere, and occupying a space of one foot square and one inch deep over all.

As regards efficiency, we will have the advantages of the present system under all conditions. For long runs upon the level we will, by a suitable switch, connect the driving motors directly to the line and secure an efficiency of 90 per cent. for our motor.

As regards depreciation, we will have the advantage of no rheostats or controlling switches to burn out and with no sparking and no connection with the field circuit we will have the minimum liability of burning out armatures.

Leaving the car, let us now consider the line. It will be evident from what we have seen that we can reduce the amount of copper to one-half the present requirements, as we never will require the enormous currents at present called for in starting and upon heavy grades. Or, to put it in another way, with the existing conductors we could run twice as many cars as at present, with the same loss in the conductors.

Now, let us look at the generators and the prime movers, whether steam engines or water wheels. Under existing systems for roads of from five to ten cars it is necessary to instal about 20 I.H.P. (rated at ¼ cut-off) per car and about 16 kilowatts per car in generators. Also about 20 H.P. per car in boiler capacity. This large equipment is necessitated by the occasionally very large demand for power and the inefficiency consequent upon this. Under the proposed system it is not necessary to provide power in excess of 15 H.P. for any car under any conditions; and since in practice most of the cars will be operating at less power than this, we need only instal engine, dynamo and boiler capacity of 8 H.P. per car, instead of 20. Or, to express it another way, we can operate with existing boilers, engines and dynamos at least double the number of cars they can at present supply.

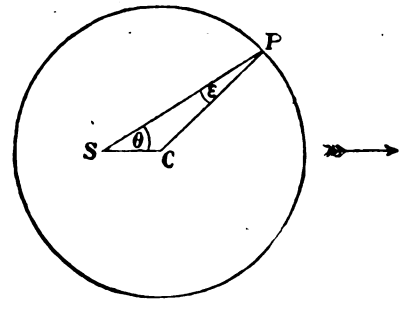
The features of the proposed system which seem, at first sight, to be very objectionable, are:—The increased cost of the car equipment, and the fact that we are adding an additional machine, having two fields, two armatures, and three bearings; but, as we have seen, there is only an apparent increase in the first cost, for the saving in the generators and distributing plant far exceeds the additional cost of the car equipment; and the use of the motor-generator for elevators, travelling cranes, &c., has demonstrated that, as regards the attention it requires and the depreciation it suffers, it has a marked advantage over the rheostat or commutated field used in the present methods of operation.

PHYSICAL SOCIETY.

At the ordinary meeting of this Society, held on the 27th ult., Prof. Oliver Lodge, F.R.S., read a Paper

"On the Present State of our Knowledge on the Connection between Ether and Matter."

Referring to difficulties arising in connection with the aberration of light, on the supposition that the ether is carried along by the earth in its orbits, Dr. Lodge referred to experiments of Klinkerfues, Sir G. Airy, and Hoek. The results of these tests were of a negative character, but appeared to show that surveying operations are unaffected by the relative motion, if any, of the earth and the ether. Other experiments by Arago, Maxwell, and Mascart lead to the conclusion that the ether is at rest with regard to the earth; but the apparently simple nature of aberration makes this view a difficult one to hold. Fizeau's well-known experiment on the effect



of moving water on the velocity of light, which has since been confirmed by the more accurate measurements of Michelson, practically establishes the truth of Fresnel's hypothesis—that only the excess of the ether which a substance possesses over surrounding space moves with the body. Looked at in another way, however, these experiments raise a difficulty, for, as all water is moving with the earth, light should be hurried or hindered according to the direction in which it passes through. This effect doubtless exists, but the result has never been experimentally detected, although carefully searched for by Babinet, Hoek, Jamin, and Mascart. From these and similar experiments the author is led to the conclusion that the ether is either stagnant or has a velocity potential.

In moving ether it was necessary to define a ray, and Lorentz's method is the best. Suppose C P represents the velocity of light (V) in still ether, and S C the velocity of the ether (v), then a disturbance originating at S will travel along S P, which is the direction of the ray, whilst C P is the wave normal. In the above figure,

$$\frac{\sin\varepsilon}{\sin\theta}=\frac{SC}{CP}=\frac{v}{V}=a,$$ the constant of aberration.

The velocity along the path of the ray is S P. Calling this velocity V', we have

$$V'=V\cos\varepsilon+v\cos\theta.$$

The path of a ray is determined by the time of journey being a minimum, and the formula

$$T=\int_A^B\frac{ds}{V}=\text{a minimum},$$

Digitized by Google

is the equation to a ray, where A and B are the extremities, and ds an element of the path. If the ether be moving, V′ must be substituted for V, and we get

$$T' = \int_A^B \frac{ds}{V\cos\epsilon + v\cos\theta} = \text{a minimum.}$$

This integral can be written exactly—

$$T' = \int \frac{ds}{V}\frac{\cos\theta}{1-a^2} - \int \frac{v\cos\theta}{V^2(1-a^2)}ds = \frac{T\cos\theta}{1-a^2} - \int \frac{v}{V^2}\cdot\frac{\cos\theta}{1-a^2}\cdot ds.$$

The last term is the only one involving the first power of ether drift, and it vanishes in case there is a velocity potential; for, since $v\cos\theta\frac{d\phi}{ds}$, where ϕ is the velocity potential, it may be written $\frac{\phi_B - \phi_A}{V^2(1-a^2)}$; and so its value depends only on the end points and not on the path. If these points are the same, *i.e.* the contour is closed, it becomes zero, and reconciles all the experiments hitherto made. It must be admitted, however, that if a is not a constant, the question is again opened, but there is no reason to suppose it can vary in the same horizontal plane. If the medium be changed, V becomes $\frac{V}{\mu}$, and, in order to retain the same velocity potential in the changed medium, v must become $\frac{v}{\mu^2}$, which is Fresnel's law. Hence the author pointed out that the velocity potential condition includes Fresnel's law as a special case. It can, in general, be inferred that *no first order optical effect due to terrestrial motion can exist in a detectable form.* It is always compensated by something else. Quantities of the second order of magnitude must, therefore, be attended to. From the first equation above, it follows that

$$\cos\epsilon = \sqrt{1 - a^2\sin^2\theta},$$

and the time of journey in moving ether is given by

$$T' = T\frac{\sqrt{1-a^2\sin^2\theta}}{1-a^2},$$

where T is the time if everything were stationary. This is, in brief, the theory of Michelson's recent experiment. If the light travels along the ether drift, $\theta = 0$ and $T_1 = \frac{T}{1-a^2}$; whilst if $\theta = 90°$, $T' = \frac{T}{\sqrt{1-a^2}}$. Therefore the velocity along the ether drift should differ from that across the drift in the ratio of $\sqrt{1-a^2} : 1$. This point has been very carefully tested by Michelson, but nothing approaching to a quarter of the theoretical effect was observed. His negative result would seem to preclude any relative motion, even irrotational, and shows that the ether is at rest relative to the earth's surface. On the other hand, the author has recently made experiments on the influence of rapidly-rotating steel discs on the ether, which prove that the ether is not affected by the motion of contiguous matter to the extent of $\frac{1}{100}$th part of the velocity of the matter. Thus these two experiments are at present in conflict. Prof. Fitzgerald has suggested a way out of the difficulty by supposing the size of bodies to be a function of their velocity through ether.

THE PARIS-NEW YORK CABLE COMPANY.*

The Board of Directors nominated at the meeting of May 31st summoned the Executive Council of the Compagnie Française du Télégraphe de Paris à New York before a Judge in chambers in order to oblige that body to surrender its duties and hand over the management. The real Board of Directors taking its stand on the flagrant illegality of the above meeting, which was held contrary to the statutes by a group of shareholders, asked that the Judge in chambers should declare himself incompetent to deal with the matter. The Judge acceded to this request. The Board also summoned the self-elected Directors before the Tribunal de Commerce. The following is an extract from the summons, giving an epitome of the whole matter and of the claims of the real Board:—"The Board of Directors of the Compagnie Française du Télégraphe de Paris à New York had, in accordance with the statutes, called a general meeting of the shareholders for May 31st, in the Salle Kriegelstein, Rue Charras. A few days before the date fixed for the meeting a number of irregularities were discovered in the share register; irregularities of such gravity that they might have led to the annulment of the proceedings, and which already had given rise to protest on the part of some of the shareholders. Amongst these irregularities may be mentioned a distribution of shares to fictitious shareholders which would have vitiated the voting. The Board then decided on its own responsibility to call a fresh meeting for July 12th next, and to take the necessary measures to ensure the genuineness and regularity of the resolutions which will be put at this new meeting.

"It had come to the knowledge of the Board that a group of shareholders deemed themselves competent to meet on May 31, 1892, at the Salle Flaxland, and to hold there a sort of meeting, at which the shareholders present amused themselves by dismissing the Board of Directors and nominating a new Board; and the members of this new Board did not hesitate to summon the Executive Council to hand over the management and the moneys of the Company.

"These illegal proceedings having been very prejudicial to the plaintiff Company, there are grounds, the irregularity being proved, for condemning each individual member of the so-called Board, elected on May 31, 1892, to pay damages.

"For these reasons it was held that those who were summoned met on May 31, 1892, and proceeded to dismiss the Board of Directors and to nominate a new Board, without any right to do so, and in a manner contrary to the statutes, that MM. Magne, Bovillez, Bécue, Homberg (Georges), de Lussigny, Hurtado, and the Vicomte de la Moussaye et Tuck had no right whatever to intervene in the management of the Compagnie Française du Télégraphe de Paris à New York, and that each of them be condemned to pay 100,000frs. damages and costs. Also that the execution of this order should be carried out, notwithstanding opposition or appeal, all rights and means of action being reserved."

* From the *Moniteur Industriel* of June 11th.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—THURSDAY, JUNE 16TH.

Select Committee on the Telegraphs Bill.

On Thursday last week the Chancellor of the Exchequer presided over the Committee; and Mr. J. S. Forbes, Chairman of the National Telephone Company, gave further evidence.

Sir JAMES FERGUSSON put it to the witness that when he said Parliament was to some extent responsible for the very imperfect development of their system, he did not mean that Parliament was responsible in respect of the single-wire system, which was begun in the early days, and he must be himself sensible that except in cases where the traffic was small it was desirable to alter it.

The WITNESS said there was no doubt the efficiency of the system, and its expansion, had been greatly hampered for a number of years by a want of power in the hands of the telephone companies. In such crowded areas as London, Liverpool, and other large towns, a metallic circuit was absolutely necessary; that involved underground wires and interference with streets, and therefore more powers in respect to the opening of streets for the laying of wires. A Committee of Parliament in 1885 determined that the free development of the telephonic system was essential to the public convenience, and that it was inevitable that powers must be given; but they never have been given. Although that Committee reported in March, 1885, now in June, 1892, the companies were without a single addition to any powers they had ever had, and the powers which they possessed were only by sufferance. He was himself satisfied that the public must have the telephonic system expanded, and made as good as it could be. If every landowner, every householder, and every small local authority was to stand in the way and dictate terms they would not get that done.

Sir JAMES FERGUSSON: Your licence would be infinitely more valuable if you had those powers.

The WITNESS: No doubt; the public service would be more efficient and the public revenue greatly benefited by the expansion in the shape of royalties. In so far as the Bill was intended to increase their powers and facilities, they were in favour of it, and had themselves brought in a Bill which was based on the necessity of having those powers; but, as Sir James understood, that Bill had been kept back in view of the Government Bill. They had asked the Government to introduce an amendment into their Bill by which the companies would be permitted, in the first place, if they could, to make an agreement with the local authorities to lay underground wires, the Post Office stepping in if the Company should fail to make such agreements. It was greatly in the interest of the telephonic business in which they were to become partners, so to speak, that the Post Office should be able to take action. It was much better that it should be in the hands of the Postmaster-General than in the hands of half-a-dozen companies. As an instance of the necessity of some such powers being given, he said that the National Company had been for many months under contract to carry telephonic communication with Reading, notably under a contract with Messrs. Huntley and Palmer, and had agreed upon terms with individuals and a great number of local authorities, but one authority declined point-blank to come to any arrangement, and, consequently, they could not carry out the desired communication. The 160,000,000 messages which the Telephone Company carried were in the nature of conversations, and, of course, included replies as well as messages.

Sir JAMES FERGUSSON: Your proposal with regard to the purchase of the Company's trunk lines is that they should be purchased at the cost price as they stand in the Company's books, along with obligations as to wayleaves?—Yes.

Now you next touch upon a difficult point. You ask for the exclusive use of your present lines, in case of their purchase, and also that the Post Office should provide such additional trunk lines as the Company may demand.

The WITNESS said he should try to put that matter plain. They had at all events in their Company some regard for contract, and they had induced a great number of their subscribers to come on to their local

Digitized by Google

exchange, in consideration, not so much of the convenience of the local exchanges, but of its connection with outside areas, and they had put up wires from time to time to meet that convenience.

Sir JAMES FERGUSSON: That being fully understood, I was going to ask you whether you do not recognise, in the case of the Post Office taking over your trunk lines, they will have at present no other exchanges to provide for, but that the extension will chiefly be in connection with your own business.

The WITNESS said that he felt that he must see that the subscribers were not damaged by any arrangement entered into with the Post Office. In reply to the Chairman he said that he qualified his statement that he would be willing to receive the book value of the trunk lines, by saying that, in some shape or other, they should receive an equivalent for the unearned increment of the 19 or 20 years that yet remained of the term of their licence, which he suggested should be in the shape of an extended rm.

Mr. WALLIS, a Director of the New Telephone Company, said that his Company were willing to enter into the Government scheme on certain conditions. He was perfectly convinced that the Government proposals would be a great benefit to the country.

Mr. WINTERBOTHAM, solicitor to the National Telephone Company, gave evidence as to the amendments that were required in the Bill from the point of view of his Company.

Mr. FRERE, representing the Bedford and Portman estates and other property owners, suggested that the Bill should be amended in regard to the matter of costs on the appeal before the Railway Commissioners, so that if an owner refused consent to the laying of lines on his property, and the refusal were appealed against, the Railway Commissioners should be bound to award costs against the beaten party. They also thought it unfair that where a private owner might have made certain terms with the companies, they should not continue to have the advantage of the bargain which they had made. The owner might have given his consent to the placing of a wire on his property on condition of receiving a rental of £5 or £10 a year, but under the Bill that was an arrangement which might be upset.

Sir JAMES FERGUSSON said that might have been a bargain imposed upon the Telephone Company which had no statutory rights, such as the Post Office had or desired to have. On the Post Office acquiring the trunk lines surely it might be allowed to reopen such a previous agreement made under great disadvantages with the Telephone Company, and this Bill would enable them to re-open it before a proper tribunal. The private owner might have extracted extreme compensation or conditions from the Company because the Company had no statutory position.

The WITNESS said that might be so, but to do so would be for Parliament to take away from them that which they had got by means of bargain.

Mr. BAKER (who said he represented 150 local authorities) said that if any alteration in Clause 5 relating to local authorities were contemplated, he should desire to place their case before the Committee.

The Committee consulted in private for some time, at the end of which

The CHAIRMAN announced that the Committee were of opinion that it was desirable and fair to the parties more or less interested in the Bill that they should know the decision at which the Committee had arrived. The Bill had been passed by the Committee substantially as it stood, with some amendments, which would be reprinted, so that the public might be able to see what changes had been made. The Chairman further stated that the Committee had also agreed upon a special report, which he proceeded to read, and which appeared in our last issue.

The Electric Railways.

Yesterday (Thursday) the Marquis of Waterford's Committee commenced the inquiry into the Baker-street and Waterloo scheme, the only opponents to the Bill being the Metropolitan and South-Eastern Railway Companies. In the course of the proceedings the latter Company were arranged with; and the Committee having intimated that they were satisfied with the evidence given by the promoters, the only point remaining was in relation to the manner in which the Baker-street Station of the Metropolitan Railway was affected, and clauses dealing with this point were considered.

LEGAL INTELLIGENCE.

Pink v. Electricity Supply Company for Spain (Limited).

This was an action for wrongful dismissal and consequent damages. The plaintiff was engaged by the defendant Company under contract to act as resident engineer in Madrid. Being unable to agree with the manager in Spain on technical matters, plaintiff, after an appeal to the Directors in London, offered to resign, but was thereupon dismissed by the manager. He returned to London under protest, and after attempting an amicable settlement, commenced the present action. The case was finally settled out of court, by the defendants paying three months' salary in lieu of notice, first-class travelling expenses, and all costs.

The Plaintiff asks us to state that he has received a letter from the defendant Company, in which the Directors regret the termination of the plaintiff's engagement with the Company, and recognised his endeavours in the Company's behalf while acting for them in Spain. They ascribe the differences with the manager in Spain as mainly due to the want of a common language. The plaintiff is further credited with the carrying out of important economies in the working of the Company's central station.

Atkinson v. Stephens, Smith and Co.

In the High Court, on Saturday and Monday last, the Lord Chief Justice and a special jury had before them an action brought by an apprentice to recover his premium of £100, which had been paid to the defendants under an agreement dated November 9, 1889. The plaintiff's case was that, wishing to become an electrical engineer, he went to the defendants' works at Cuba-street, Millwall, and an agreement was entered into between them whereby he was to pay £100, and the defendants undertook to take him into the electrical department of their works for three years, and to teach and instruct him in electrical engineering in all its branches, special attention being given to imparting instruction in mechanical drawing, testing, and practical knowledge of electric motors and dynamos. The plaintiff was to attend at the works from 9 a.m. to 5 p.m., and was to receive 8s. a week salary. When the plaintiff entered upon his duties the defendants told him to watch the workmen doing their work, and they also set him to do mechanical work connected with electric motors. The plaintiff objected to this class of work, desiring to be taught the theoretical part of the work. The plaintiff also complained that there was not sufficient electrical work going on to teach him his profession.

Evidence was called for the plaintiff, including two other apprentices at the defendants' works, who stated that there was not work enough there to keep them sufficiently employed.

On the other hand, for the defendants, it was proved that during the time the plaintiff was with them they had a great number of electrical jobs on hand, quite sufficient to give the plaintiff all necessary instruction, but that the plaintiff only attended from three to five hours per week; they also contended that they only undertook to teach practical work, and not the theoretical science of electricity.

In the result, the jury returned a verdict for the defendants.

Denby v. Scott and Mountain (Limited).

In the Second Division of the Court of Session (Edinburgh) on Wednesday last week, the Lord Justice Clerk and Lords Young, Rutherfurd Clark, and Trayner gave judgment in the above action.

In the Outer House Lord Kyllachy, as previously reported (*The Electrician*, Vol. XXVIII., p. 152), gave judgment on December 9th last in the action by John Denby, stereotyper and electrotyper, 4, Swinton-row, Edinburgh, against Ernest Scott and Mountain (Limited), engineers, Close Works, Newcastle-upon-Tyne, for £500 damages for alleged breach of contract, he having been supplied with a dynamo machine for his business as an electrotyper, which, he averred, was unfit for the purpose for which it was furnished. Lord Kyllachy, after proof, assoilzied the defenders with expenses, holding that the pursuer had not proved that the dynamo was disconform to contract. Against this judgment the pursuer reclaimed to the Second Division. On the reclaiming note the pursuer asked leave to lead additional proof on a condescendence of *res noviter*, in which he averred that since the proof he had ascertained that certain tests were made of the machine in the defenders' works at Newcastle before it was supplied to him, which would demonstrate that the machine was not suitable for electrotyping at the normal speed of his engine. The additional proof was led before Lord Rutherfurd Clark, on March 12th, when it was proved that the machine was now in Messrs. Chambers' works in Edinburgh. On being tested it gave exactly the same when tested at Newcastle, and further that on being turned to electrotype the work it produced was first-class. The Division to-day refused the reclaiming note, assoilzied the defenders, and found them entitled to further expenses.

JUDGMENT.

Lord YOUNG, who gave the leading opinion, said it was much to be regretted, looking at the expense involved in the bringing of the action, that the pursuer had given an order for a machine before he knew how to work it. His lordship was of opinion that if the pursuer intended to reject the machine as disconform to contract, it was not done timeously, but on the proof his lordship said the evidence disclosed that the defenders had supplied the machine contracted for, and that it was perfectly suitable for electrotyping.

The other Judges concurred.

CORRESPONDENCE.

THE CITY AND SOUTH LONDON ELECTRIC RAILWAY

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the present Session of Parliament no fewer than six Bills have been introduced authorising the construction of new underground railways in London to be worked electrically, or the extension of those for which Acts of Parliament have already been obtained. Three of these Bills have passed through the House of Commons, and are in an advanced stage in the Upper House. The present time, therefore, is opportune for drawing attention to the results which have been attained with electric traction on the only railway in the world on which it has been adopted on an extensive scale, and the working of which during the eighteen months it has been open for public traffic is the basis upon which the promoters of the present

Digitized by Google

schemes found their application for Parliamentary powers, and from which they must in the future seek the confidence of the public. That the City and South London line has been a success in the system of traction adopted is conclusively shown by the mere fact of the present schemes being brought forward, and has moreover been abundantly proved by the evidence given before the Joint Committee of both Houses appointed to consider the proposed lines from the point of view of their general public utility, and also by the evidence given as the Bills passed through Committee in the Lower House; but, as you yourself point out in a recent editorial note, no authentic information has been forthcoming as to the actual results achieved, nor any explanation of any shortcomings in its working which must be obviated in the future.

The limits of a letter do not permit the discussion of the engineering features of the electrical plant adopted; but as my firm designed and constructed the whole electrical equipment of the railway, the present occasion is not inopportune either in time or place for me to give a brief account of the history of the first year's working and of the results achieved, leaving for some other occasion a discussion of the technical details.

The City and South London Railway Company, then known as the City of London and Southwark Subway Company, obtained its first Parliamentary powers in 1884 for the construction of a subway from King William-street in the City to the Elephant and Castle in Southwark. The success, however, of Mr. Greathead's beautiful system of constructing the tunnels, now familiar to all interested in engineering matters, had been so conspicuous that the Directors obtained powers in 1887 for an extension to the Swan Inn at Stockwell. Further powers have since been obtained for an extension southwards to Clapham, but this portion of the line has not yet been constructed. It was originally intended that the Subway should be worked on the cable system, and contracts were actually arranged for this purpose, but the progress of electrical traction in the interval made it necessary to reconsider the system of traction to be adopted. The Bessbrook and Newry Tramway (more correctly described as a railway) had been equipped with electrical plant by Messrs. Mather and Platt, and had been running with perfect regularity for three years. The weight of the trains on this line were but little less than the weight of the trains proposed for the South London line, and the cost of haulage had been proved not to exceed 4d. per train mile, although the mileage was small, and consequently fixed expenses high in proportion. The success attending the Bessbrook line induced Messrs. Mather and Platt in 1888 to approach the Directors of the City and South London line, and to make definite proposals to them for working their line electrically, instead of by cable. After long consideration the cable system was finally abandoned, and Messrs. Mather and Platt's scheme accepted in its entirety. Their proposal was accompanied by an offer to work the line for a limited period or to guarantee the cost of traction for two years. The locomotives were to be designed for drawing trains consisting of three carriages accommodating 100 passengers, and weighing 4¼ tons each, and the generating plant was to be sufficient for working a service of 20 trains per hour. A contract was entered into with Messrs. Mather and Platt, in January, 1889, and their guarantee accepted that the cost of haulage, exclusive of driver's wages, should not exceed 3½d. per train mile for the maximum service proposed, viz., 384,800 train miles in the half-year, and according to a sliding scale, if the mileage were more or less, increasing up to 7⅛d. per train mile for 188,666 miles, the actual mileage accomplished.

The works were completed in November, 1890, and on November 4th were formally inaugurated by the Prince of Wales, accompanied by the late Duke of Clarence. On December 18, 1890, the line was opened for public traffic; and has now completed eighteen months' running. During this time Messrs. Mather and Platt's locomotives have run more than 500,000 miles, and have provided for a traffic of more than 7,000,000 persons; but this statement alone does not fully represent the work which has been demanded from them. Owing to the carriages being made stronger and heavier than originally designed, the actual weight of each carriage being 7 tons instead of 4¼ tons, the weight of the loaded trains was increased to 42 tons, or more than 40 per cent. heavier than the trains for which the locomotives were designed. Of this great increase in the loads which their locomotives were to draw, Messrs. Mather and Platt had no intimation until after all the locomotives were constructed and delivered, and arrangements had been made for the opening of the line. Under such unexpected circumstances the locomotives have at times been overstrained, and delays to the traffic resulted, and the wear and tear has proved somewhat greater than originally anticipated, yet the record of work done by the electric locomotives in comparison with the work done by steam locomotives is extraordinary. Leaving out of consideration one of the locomotives of special type made for the purpose of testing its comparative efficiency, the average mileage made by the remaining 13 locomotives during the first year of work exceeded 27,000 miles. On the Metropolitan District Railway the yearly average of their locomotives appears to be less than 20,000 miles. The cost of working has proved equally satisfactory. Although the formal guarantee of Messrs. Mather and Platt was not taken up on account of the carriages failing to comply with the specification upon which they were requested to base their calculations, yet their estimate of cost has been abundantly justified. During the second six months of working, according to the published half-yearly accounts, the cost of locomotives and generating power, including wages, repairs, and renewals, was £6,199 for a mileage of 188,666, or less than 8d. per mile. If allowance be made for the driver's wages, which were excluded from the original estimate, this is equivalent to about 5½d. per train mile, 25 per cent. less than the amount guaranteed by Messrs. Mather and Platt, although the weight of the trains had been increased 40 per cent. These facts are the more striking when the difficulties of adequate and regular inspection of the rolling stock of a line entirely underground are considered, difficulties which do not obtain in the case of any ordinary railway; and when it is further remembered that the entire system of working was novel, to which the employés of the Company were unaccustomed, and for which they had received no special training.

Under the able management of Mr. Basil Mott, the Company's engineer, and Mr. T. C. Jenkin, the general manager, it is probable that the working expenses will be still further reduced, while the mileage and traffic receipts are being steadily increased.

The distinguishing feature of Messrs. Mather and Platt's locomotive is that the armature is constructed directly upon the axle, and the magnets supported partly upon the axle and partly upon the frame. Probably this design, obviating all gear, and reducing the mechanism to the simplest elements, has contributed more than anything else to the successful working. For the heavier trains which will be required for the working of the new lines there will be no difficulty in designing heavier and more powerful locomotives on the same principle. In the schemes now under consideration, Mr. Greathead is proposing larger tunnels, 12ft. in diameter, instead of 10ft., as in the case of the City and South London line. This will greatly facilitate the construction of larger locomotives and more commodious and comfortable carriages, which are the chief points necessary to ensure the success of the new undertakings.—Yours, &c.,

EDWARD HOPKINSON.

Salford Iron Works, Manchester, June 21, 1892.

CRYSTAL PALACE EXHIBITION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Do you happen to know if there is any reason why the jury appointed to examine, &c., the exhibits at the Crystal Palace should decline to undertake the examination and testing of meters?

There is probably no subject of greater interest and importance just now than the means by which consumers are to be charged for the current they take. It seems incomprehensible that the jury should decline to concern themselves with it.—Yours, &c.,

S. Z. DE FERRANTI.

[This is referred to in our Notes.—ED. *E.*]

RUNNING ALTERNATORS IN PARALLEL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the correspondence in your paper on this subject it may interest your readers to know that within a few months of the establishment of this station three years ago, we have been in the habit of running regularly with the Mordey-Victoria alternators in parallel. Whenever the load exceeds that of one machine we run in this way, and have never experienced any trouble.

As a matter of fact, we could not run in any other way if we wished to do so, as we have only one main into the town, and the switchboards are arranged on the standard plan of the system, by which no provision is made for any other mode of working. We may add that our alternators are two of 37·5 kilowatt, and three of 75 kilowatt, and that the engines are also of the Brush Company's make.—Yours, &c.,

JAMES SHEPHERD, Works Manager,
The Bournemouth and District Electric Supply Company.

Bournemouth, June 20, 1892.

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

TENDERS INVITED.—The Secretary of State for War invites tenders for the purchase of Matheson's ebonite connectors and Morse's recorders, now lying at the Royal Arsenal, Woolwich, where they can be viewed, and forms of tender and all information can be obtained on application to the Commissary-General of Ordnance, any week day between 10 a.m. to 1 p.m. and 2 p.m. to 4 p.m. (Saturday afternoons excepted). Tenders are to be sent in to the War Office, Pall Mall, S.W., by 12 o'clock on Monday, 4th July, addressed to the Director of Army Contracts. Further information is given in our advertisement columns.

——— The Gas Committee of the Manchester Corporation invite tenders for the electric wiring of the Town Hall. General conditions and specifications can be obtained on written application to Mr. C. Nickson, superintendent of the gas department, Town Hall, accompanied by a deposit of two guineas, and tenders must reach the Chairman of the Gas Committee by 10 a.m. on the 5th prox.

———Tenders are invited by the Huddersfield Corporation for the supply of an arc and incandescent plant at the Sewage Works. Specifications and forms of tender may be obtained from Mr. A. B. Mountain, the borough engineer, to whom tenders are to be delivered not later than Saturday, the 2nd prox.

———The Material Bureau of the Königliche Eisenbahn Direction, Hanover, invite tenders for 10,000 zinc and 7,000 copper elements, 78,800 kilogrammes of galvanised iron wire of various diameter, and 4,000 metres of 4mm. steel wire. Tenders are to be in by the 30th inst.

———The Director-General of Posts and Telegraphs of Roumania will on July 4th open such tenders as may be received by him for the supply of 10,000 large and 20,000 small porcelain insulators.

PLANT FOR SALE.—Messrs. Wheatley Kirk, Price and Goulty announce in our advertisement columns that they have for sale several engines suitable for electric light driving (including a very fine pair of new vertical Corliss engines, guaranteed to indicate 10,000 H.P.), two combined Willans engines and dynamos, about fifty dynamos and motors, a 100 I.H.P. Babcock-Wilcox boiler, and a small electric light installation, comprising a Crompton dynamo, 26 E.P.S. 11-L. glass cell accumulators, instruments, switches, &c.

NEW FIRMS.—Mr. Arthur Bergtheil (late manager of the Wenham Company's electrical department) and Mr. H. Wilson Young (formerly with Messrs. Clarke, Chapman and Co.) have commenced business as electrical engineers and contractors at 13, Walbrook, London, E.C.

——— Messrs. McInnes and Co. have commenced business as manufacturing electricians and electric light engineers at Magenta-street, Woodgate, Leicester.

VAUGHAN-SHERRIN ELECTRICAL ENGINEERING COMPANY (LIMITED). At meetings of the shareholders of this Company held on May 19th and June 10th, it was resolved and confirmed that the Company be voluntarily wound up, and that Mr. Septimus Hedges, 15, George-street, Mansion House, E.C., be the liquidator.

BANKRUPT.—A receiving order has been issued in the estate of Walter Philip O'Reilly, of Edgware-road, described as a manufacturing electrician.

DISSOLUTION OF PARTNERSHIP.—Messrs. Nicholson, Bolton, and Tyler, carrying on business at 100c, Queen Victoria-street, E.C., as electrical and mechanical engineers, have dissolved partnership so far as regards R. P. Bolton.

MR. WALTER LEAKE.—It is intended to adopt the electric light throughout St. Patrick's Training College, Drumcondra, Dublin. Mr. Walter Leake has been appointed Consulting Electrical Engineer to the College.

SADDLE STAPLES.—Staples with a saddle of vulcanised fibre which have been in use for some time are now being made by Messrs. Mosses and Mitchell. They should prove useful in electric bell and telephone work in dry places, since the fibre will prevent cutting of the wire by the metal. We, however, disagree with the use of vulcanised fibre for insulating purposes in electric light work, and with the use of staples for holding electric light wires. The mechanical qualities of vulcanised fibre are, of course, well known.

MESSRS. ERNEST SCOTT AND MOUNTAIN (LIMITED).—This firm have just completed an electric pumping plant for the North Seaton Colliery, the pumps being the largest of the kind that have yet been made.

MR. W. S. SARGEANT.—We learn that Mr. Sargeant has applied for a patent for an electric port, starboard and mast-head light in one fitting. Two switches are used, one controls the port and starboard light, and the other the light at the mast-head. It is stated that excellent results have been obtained from the tests to which this lamp has been put, and four are being made for use on electric launches now built or building.

MESSRS. ARTHUR B. GILL AND CO.—Mr. Arthur B. Gill, trading under the above title as an electrical engineer, of 36, Parliament-street, S.W., Eastdown Park, Lewisham, and Grove Park, has filed a deed of assignment of his property for the benefit of his creditors, the principal of whom are:—

Aërated Bread Company (Limited), London	£100	0	0
Beal (S.) and Co., London	29	0	0
Best and Lloyd, Birmingham	25	0	0
Buller, Jobson and Co. (Limited), London	65	0	0
Edison & Swan United Electric Light Co., London	80	0	0
Harris (J. F.) and Co., London	22	0	0
Hindley, E. S., Bourton	37	0	0
Henley's (W. T.) Telegraph Works Co. (Limited), London	312	0	0
International Publishing Co., London	32	0	0
Johnson and Phillips, London	33	0	0
Lawrence, H. E., London	55	0	0
Nalder Bros. and Co., London	27	0	0
Peel, Captain Robert, Beckenham	3,806	0	0
Bankers' claim	431	0	0
And creditors under £20.			
Total	£5,418	15	1
Secured	416	0	0
Net assets	4,984	0	5

GRANGE SYNDICATE (LIMITED).—The following are the principal creditors of this Company, now being wound up:—

Courtenay and Co., London	£150	0	0
Elliott and Co., London	39	3	6
Hollick, William, London	21	0	0
Hopkinson, Dr. J., London	39	19	6
Rawson, F. L., London	192	16	4
Woodhouse and Rawson United (Limited), London	11	19	2
And other creditors under £20.			
Total	£520	4	3
Fully secured creditor	22	0	0
Liabilities on bills	34	0	0
Preferential creditors	27	1	11

NOT ELECTRICAL.—The Great Eastern Railway Company have just issued their annual list of farm houses and country lodgings in the counties served by the Great Eastern system, including Essex, Hertfordshire, Cambridgeshire, Suffolk and Norfolk. The list is in tabulated form and gives a quantity of information which will be found of the greatest possible use at this season of the year to those seeking health and change. This must be our excuse for calling attention to a publication not of an electrical character.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

May 31, 1892.

10,303. W. P. CARSTARPHEN, Jun. London. Improvements in electrical reciprocating tools.

10,334. R. KENNEDY. Glasgow. Improvements in dynamo-electric generators and motors.

10,367. H. SANCHE. London. Improvements in connections and terminals for electric and other wires and cables.

10,388. E. FREUND and L. BRISTÖL. London. Improvements in secondary batteries.

June 1, 1892.

10,430. R. WOOD. Manchester. An improvement in electrical insulating sheet. (C. W. Jefferson and Rupert R. St. John.)

10,451. R. N. LUCAS, A. J. MAYNE, and A. G. NEW. London. An automatic switch for electric-current transformers.

10,456. H. H. LAKE. London. Improvements in the manufacture of conducting wires for electricity. (Madame V. Hannetelle, *née* Hortense Chapuis, France.)

10,466. Sir C. S. FORBES. London. An improved telephone combination.

June 2, 1892.

10,472. J. A. EWING. Cambridge. Improvements in apparatus for electrical and magnetic measurements.

10,477. W. W. HORN. London. An improved cut-off for electrical purposes. (J. P. Wooley, Canada.)

10,478. W. GRIERSON. Glasgow. Improvements in electric generators.

10,484. J. SAYERS. Derby. An improved method of regulation of the potential difference of electrical conductors.

10,520. A. V. BORCKXSEL. London. Improvements in and connected with electrical batteries.

10,524. A. H. S. DYER. London. Electrical insulating sheet.

June 3, 1892.

10,544. G. SACCO. London. The extra rapid telegraphic apparatus with inverted currents.

10,602. A. MYALL. London. Improvements in telephones. (W. S. Harrison, China.)

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

8,793. HANUSSE AND BORREL. Electrical signalling.

10,434. SINGER. Electric meters.

12,018. WILSON. Electrical gear for steering ships, &c.

12,491. BAKERS and others. Rheostats.

12,529. EDMUNDS. Distributing electric currents.

12,605. LAKE. (Lacombe and Co.) Electric batteries.

14,517. SIEMENS BROS. AND CO. (LIMITED). (Siemens and Halske.) Microphones.

15,337. MUIRHEAD. Electrical condensers.

1892.

2,488. TRIPPE. Electric lighting.

7,253. DUFFY. Generating electricity.

COMPANIES' MEETINGS & REPORTS.

Western Counties and South Wales Telephone Company (Limited).

An extraordinary general meeting of this Company was held on Tuesday afternoon at the Grand Hotel, Bristol, to consider resolutions for the amalgamation of the Company with the National Telephone Company (Limited). Mr. C. Nash, Chairman of the Directors, presided.

Mr. H. F. LEWIS (General Manager and Secretary) having read the convening notice,

The CHAIRMAN moved the first resolution, as follows:—

"*That the agreement submitted to this meeting, and expressed to be made between this Company and the National Telephone Company (Limited), for the amalgamation of the two Companies by a transfer of the business and property of this Company (with certain exceptions) to the National Telephone Company (Limited), be, and the same is, hereby approved.*"

One reason, he said, why it was most important that the Company should be united to the National was that they might have joint action. Seeing that five out of the six English telephone companies had been amalgamated, he thought it would be very undesirable for that Company to stand aloof. Joint action was desirable, among other things, in dealing with the Post Office, and in connection with the extensive changes that were now being introduced in telephone matters. They were on the eve, probably, of a revolution in telephone work. The Directors had made the best terms they could with the National, and they were unanimously of opinion that the shareholders would be doing right in confirming the provisional arrangement which had been made, and in this they were glad to know the great bulk of the shareholders agreed. It had been pointed out that 6 per cent., which was the dividend now payable on the National Company's stock, would yield £1. 13s. 4d. per cent. on their Company's shares if the proposed arrangement were carried out. This was more than they had paid up to the present time, and it was certainly more than they could expect to earn if the Company went on independently.

Mr. MARK WHITWILL seconded the resolution.

Mr. GEORGE WHITE referred to the letter which members of the Bristol Stock Exchange addressed to the Directors, expressing their opinion that there was no reason why the undertaking should be sold except upon proper terms, and the letter continued:—"Seeing that the present revenue of the Company exceeds the income which would accrue to the shareholders under the proposed sale, and that no return is being secured to the Company for its splendid future, we are of opinion that you will best consult the interests of the shareholders by refusing to sell the undertaking upon the present inadequate terms." To this the Directors replied that if the signatories of the memorial would give a firm offer to raise, say, £100,000 upon Second Preference shares, at such a rate of interest as would not exceed the earning power of the Company, the Directors would submit the proposal to the National Company, and suggest that they give to the Western Company an option of either accepting the terms of amalgamation now under consideration, or of raising additional capital from the continuation of the Company as a separate undertaking. In the opinion of the Directors, the reply further stated, it would be useless to propose the raising of capital without at the same time showing that it could be effected on reasonable terms. But what had happened? The Directors, instead of being prepared to discuss the matter, directly they received a letter from the members of the Stock Exchange saying "Yes, we will raise the money on reasonable terms," got out their notices sharply. He did not consider that was a proper way to deal with the question. Having thrown down the gauntlet, and asked if the members of the Stock Exchange were ready to find the money, and these gentlemen having replied, the Directors simply issued notices of the proposed sale to the National. The Directors ought to have taken time over the question and been prepared to discuss with the Stock Exchange the alternative proposals. In the letter from that body to the Directors there was a provision that the Board would have to be re-constituted, and if the Directors felt that that was a stumbling block, well and good. He moved the adjournment of the meeting for three weeks to enable the Directors to further consider their position.

Mr. McKNIGHT (Liverpool) seconded the amendment, and expressed the opinion that before any terms were discussed with the National Company ordinary shareholders ought to have had the option of finding the money necessary to carry out the business.

Mr. JAMES INSKIP, the Company's solicitor, referred to the agreement in existence between the two Companies, and said it contained a provision not only that the Company should not enter into an arrangement with the Post Office or any public department of the Government without the sanction of the National Company, but further, that whatever compensation was received should be divided between the Companies in such a manner as arbitrators should settle. In other cases the amalgamations had been with large Companies, not, as some shareholders might think, with small ones. This matter had not been rushed; the Directors had been attending to it for a long time.

In reply to a question, the GENERAL MANAGER said that nothing less than £100,000 or £150,000 would be of use to the Company, considering its future prospects.

The amendment was carried by a large majority on a show of hands.

Mr. INSKIP said that there were some gentlemen who were not entitled to vote, and the only thing to be done was to take a poll.

Mr. WHITE protested; but

The CHAIRMAN, after a brief consultation with other Directors, said he thought they must take a poll. They could not ignore the fact that a large number of shareholders had expressed their approval of the course the Directors had taken; and although a good many hands had been held up for the amendment that afternoon, they represented a comparatively small amount of capital.

Mr. INSKIP added that unless the matter were completed by August 1st the agreement would fall to the ground. If the suggestion of Mr. White was that the parties should meet and talk the matter over, he should advise the Directors to afford sufficient time for anyone who wished to discuss the question with a view to arriving at an amicable understanding; but if, as he understood it, the suggestion was that whenever the question came on there was to be a fight in a court of law the sooner it came on the better.

Mr. WHITE said he had intended asking the Directors to receive a certain number of shareholders to discuss various questions during the period of adjournment.

The Directors consulted in private for a few minutes, and on their return,

Mr. INSKIP said it had been decided to take a poll at once upon the motion for adjournment.

Mr. WHITE said he should test the legality of that course, and he suggested that those who supported him should leave the meeting with him.

These gentlemen having withdrawn, a poll was taken, and the motion for adjournment was declared lost, 87,285 votes being recorded against it, Mr. INSKIP saying that the gentlemen who had withdrawn represented about 3,000 shares.

Digitized by Google

A resolution was unanimously adopted for the winding-up of the Company voluntarily. Mr. T. A. Welton, of London, was appointed liquidator, and was authorised to carry the agreement into effect, to receive the shares agreed to be allotted, with the cash payable thereunder, and to distribute the same among the members of the Company.

A vote of thanks to the Chairman for presiding concluded the proceedings.

West Coast of America Telegraph Company (Limited).

The following report has been issued by the Directors of this Company, and will be presented to the shareholders at the meeting to be held at Winchester House, E.C., on Monday, the 27th inst., at one o'clock :—

The gross income of the Company for the year ending December 31, 1891, as shown in the balance-sheet and revenue account, was £35 624 16s. 5d., against £65,323. 15s. 4d. for the year ending December 31, 1890. Adding £2,195. 12s. 11d. brought forward from the previous year makes a total of £37,820. 9s. 4d., and deducting from this the debenture interest and all other charges, there remains the sum of £1,413. 9s. 9d. to be carried forward.

During the revolution in Chili, four sections of the Company's cables, extending from Mollendo to Caldera, were cut by the Chilian war vessels ; these cables were repaired after about two months' interruption. The southern section, Valparaiso to Serena, was closed for public traffic by order of the Government for nearly six months, and it was not until September 1st last that communication was completely restored over the Company's system.

The negotiations mentioned in the last report have been brought to a satisfactory termination, and a land line is already in course of construction between Buenos Ayres and Valparaiso, which will connect the Company's system with those of the Western and Brazilian, the Brazilian Submarine, and the Eastern Telegraph Companies, and thus meet the competition of the Central and South American Telegraph Company.

The Directors extremely regret the death, on February 19th last, of their late esteemed Chairman, Mr. Alfred Marshall, by whom the above negotiations had, up to that date, been chiefly conducted on behalf of the Company. Sir John Pender, K.C.M.G., who has taken an active part in bringing about the arrangement above alluded to, will, it is understood, continue to give it his valuable support as Chairman of the new connecting Company. Mr. J. Denison Pender, a Director of the Brazilian Submarine and other telegraph companies, has kindly consented to join the Board, and to occupy the chair of this Company, and will accordingly be proposed for election at the general meeting of the shareholders now called. This accession of strength and the amicable working arrangements with the Brazilian Companies open up a fair prospect for the future of the West Coast Company.

Mr. Henry Roberts and Mr. Frederick Walters are the Directors retiring by rotation ; both are eligible, and offer themselves for re-election. The auditor, Mr. J. Weise, of the firm of Messrs. Turquand, Youngs, Weise, Bishop, and Clarke, retires ; but, in consequence of the uncertainty of his health, does not seek re-election. Mr. John Francis Clarke, however, a member of the same firm, offers himself to the shareholders for election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

ELECTRICAL COAL-CUTTING CONTRACT CORPORATION (LIMITED).—This Company was registered on the 18th inst. with a capital of £402,000, divided into 60,000 ordinary shares of £5 each, 20,000 deferred shares of £5 each, and 2,000 founders' shares of £1 each. The objects are to enter into and carry into effect an agreement, which has already been prepared, and is expressed to be made between the Woodfield Syndicate (Limited) of the one part and the Corporation of the other part ; to acquire, develop, grant licences in respect of or otherwise turn to account the patents, patent rights, and privileges referred to in the said agreement ; to carry on in the United Kingdom all or any of the trades or businesses of colliery proprietors, coke manufacturers, coal cutters, contractors, electricians, electrical contractors, electrical and mechanical engineers, suppliers of electricity for the purposes of light, heat, sound, power, or otherwise ; and of manufacturers, suppliers on the hire, hire purchase, or any other system, hirers and dealers of and in all machinery, apparatus, plant, materials, and things required for or capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity. The signatories are :—Sir Archibald C. Campbell, Bart., M.P., Blythswood, Renfrew ; Lindsay Wood, The Hermitage, Chester-le-Street, Durham ; the Hon. George W. Winn, Nostell Priory, Wakefield, Yorkshire, colliery manager ; James R. Knowles, Westwood, Ince, near Wigan, Lancashire, mining engineer ; Septimus Rivington, Kilmeny, Wimbledon, Surrey, publisher ; Walter T. Goolden, 28, Westbourne Park, electrical engineer ; and Frank Stobart, J.P., Biddick Hall, Fence Houses, Durham.

EXPANDED METAL COMPANY (LIMITED).—This Company has been registered with a capital of £125,000, in £1 shares. Object : To acquire as a going concern the business of working certain patents and inventions relating to improvements in metal trellis or lattice work, now carried on by the British Metal Expansion Company (Limited) at West Hartlepool.

LONDON AND SUBURBAN MESSENGER AND GENERAL AGENCY COMPANY (LIMITED).—This Company was registered on the 18th inst., with a capital of £25,000, in £1 shares, to establish and carry on the business of general messengers, carriers, and agents (either in connection with the electric call system and the telephone system or one of them or not).

WILLIAM HARVIE AND CO. (LIMITED).—This Company has recently been registered in Scotland, with a capital of £30,000, in 8,000 preference and 22,000 ordinary shares of £1 each, the object being to acquire and carry on the business of William Harvie and Co., lampmakers, brassfounders, electrical engineers, &c.

ELECTRICAL STANDARDISING, TESTING, AND TRAINING INSTITUTION (LIMITED).—The annual return of this Company, made up to December 31, 1891 (no ordinary general meeting having been held in 1891), was filed on the 10th inst. The nominal capital is £10,000, divided into 1,900 ordinary and 100 founders' shares of £5 each. Seven shares have been taken up, but no calls have as yet been made ; the original signatories being the only shareholders.

LATIMER CLARK, MUIRHEAD AND COMPANY (LIMITED). — The annual return of this Company, made up to May 12th, was filed on the 19th. The Company was registered on October 22, 1883, with a capital of £100,000, in £10 shares. At the time of making up 4,709 shares had been taken up, and upon each of these the full amount had been called and paid.

CITY NOTES, &c.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—Notice is given that the coupons on this Company's Four per Cent. Mortgage Debentures to bearer due on July 1st next, will be paid on and after that date at the Alliance Bank, Bartholomew-lane, London, E.C. Coupons must be left at the Bank three clear days for examination. Warrants in payment of the interest on the registered debentures will be sent out on June 30th. The Debenture Register will be closed from Monday, the 27th, to Thursday the 30th inst., both days inclusive.

ANGLO-PORTUGUESE TELEPHONE COMPANY (LIMITED).—Coupons No. 9 of the First Mortgage and No. 4 of the Second Mortgage Debentures will be paid, less income-tax, by the Alliance Bank, Bartholomew-lane, on and after the 1st prox.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—Notice is given that the coupons on this Company's second issue of Five per Cent. Debentures, due 30th inst., will be paid on and after that date at the Alliance Bank, Bartholomew-lane, London, E.C. Coupons must be left at the bank three clear days for examination.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended June 19th were £771, as against £721 for the corresponding period of last year, being an increase of £50. The total receipts to date, from January 1st last, amount to £19,707, against £18,500 in the corresponding period of 1891, being an increase of £1,207.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company notify that the coupons due July 1st next on their Five per Cent. Mortgage Debentures will be paid on and after that date at the banking house of Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

INDO-EUROPEAN TELEGRAPH COMPANY.—This Company's branch station at East India-avenue, E.C., has been removed to 6 and 8, Lime-street Square, E.C., where it is connected by special wire with the Company's chief offices at 18, Old Broad-street, London, E.C. The branch office is open from 10 a.m. to 7 p.m., closing on Saturday at 3 p.m.

MADRID TELEPHONE COMPANY.—The revenue of this Company last year was £22,381. Of this sum £7,161 was net profit.

NATIONAL TELEPHONE COMPANY (LIMITED).—This Company have resolved, subject to final audit, to recommend the following dividends for the last half year, namely, at the rate of 6 per cent. per annum, less income tax, on the amounts paid up on the first and second preference shares, and at the rate of 7 per cent. per annum, less income tax, on the amount paid up on the ordinary shares, making, with the interim dividend already paid, 6 per cent. for the year ending April 30, 1892. The transfer books of the Company will be closed from July 1st to July 14th, both days inclusive, and the dividend warrants will be posted on the latter date.

ST. JAMES AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED). A private meeting of the founders' shareholders in this Company was held on Wednesday last at Winchester house, Old Broad-street, E.C., to which reporters were not invited. With reference to the circular issued to the founders' shareholders, and signed by Messrs. Fry, Sturdy, Kitchin and Francis, the Directors of the Company state that the proposed meeting was called without consultation with them, and that the statements in the circular were *ex parte*, and must be taken as such.

TELEPHONE COMPANY OF AUSTRIA (LIMITED).—Coupons No. 15 of the Five per Cent. Debentures will be paid, less income-tax, at Martin's Bank, 68, Lombard-street, E.C., on and after the 1st prox.

WEST AFRICAN TELEGRAPH COMPANY (LIMITED).—A balance dividend of 5s. per share is proposed by the Directors, making a total payment of 4 per cent. for the year ended December last.

Digitized by Google

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The coupons due June 20th on the debentures of this Company will be paid by Messrs. Barclay and Co., Lombard-street. Coupons should be left three clear days for examination.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the fortnight ended June 15, 1892, amounted to £2,621, as compared with £2,538 in the corresponding period of last year, an increase of £33.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended June 17, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,578.

CRICKET.—JOHNSON AND PHILLIPS C.C. *v.* CITY ELECTRIC C.C. (MESSRS. H. F. JOEL AND CO.)—This match was played on Saturday, the 18th inst., on Victoria Field, Charlton, and resulted in favour of Johnson and Phillips C. C. by 5 wickets and 26 runs. Score :—

CITY ELECTRIC C.C.—F. Joel c and b Jepson, 0 ; Goater b Reed, 0 ; W. Smith b Jepson, 15 ; Hiscock b Jepson, 9 ; Pearson b Jepson, 0 ; Youngman c Broome b Jepson, 0 ; Lowe b Reed, 4 ; Aubert b Reed, 2 ; Smith b Jepson, 0 ; Reuham b Jepson, 0 ; Barrera not out, 0 ; extras 8—Total, 38.

JOHNSON AND PHILLIPS C.C.—Jepson c Smith b Joel, 1 ; Zambra c Joel, 0 ; Craston b Smith, 11 ; Short b Joel, 1 ; Broome, not out, 39 ; Williams b Smith, 1 ; Reed not out, 4 ; Phillips, Sennett, Wall, and Riley did not bat ; extras 7—Total for 5 wickets, 64.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 737.—Vol. XXIX. FRIDAY, JULY 1, 1892. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6*

NOTES.

The correspondence between the St. James' and Pall Mall Company and the Board of Trade, which we publish *in extenso* elsewhere in the present issue, shows that at any rate the particular case of gas-meter damage in question was not due to any defect of the St. James' mains. It is natural, and, perhaps, even desirable, that the gas journals should be for ever on the alert to criticise the proceedings of electric lighting companies; but if electrical journals were to devote a proportionate amount of space to the chronicling of small beer in the shape of gas accidents, they would have but little room for anything else.

Negative results in experimental science are rather unsatisfactory, because it is impossible to say whether a certain effect is really absent; or whether it fails to be visible, merely because the apparatus is not sufficiently sensitive to detect the effect if it really exists. The only conclusion that such experiments really permits is, that the effect, if any, is less than a certain magnitude. This is surely much less satisfactory than a measurement of its magnitude, however rough.

The earliest attempts to measure the velocity of light by means of dark lanterns flashed from neighbouring hill-tops could not possibly succeed, so crude was the mode of experiment. A negative result was the natural consequence. Had Roemer, who calculated the velocity of light in 1667 from apparent discrepancies in the times of the eclipses of Jupiter's satellites, arrived at a result three times too large or three times too small, instead of a result differing only by about one-third from the most accurate measurements, his result, though very inexact, would have been of immense importance. Nobody, probably, made a greater number of negative experiments than Faraday, a large proportion of them having been made with the expectation of a negative result. All these were of immense help to him as guides; but his real advances are based on his positive results.

After a number of negative results such as those which Dr. Oliver Lodge and others have made relating to the ether theory, a strong presumption may be arrived at, through the process of elimination, if they are all accordant; but it can hardly be called a certain conclusion. Dr. Oliver Lodge, in the letter which will be found in our correspondence columns, says that "an answer 'no,' though a negative reply, may be as decided and *positive* an answer as 'yes.'" But in experimental work can we ever induce nature to say "no"? She merely keeps silent, and forces us to put up with the unsatisfactory verdict of "not proven."

In *The Electrician* for November 20, 1891, Dr. Louis Duncan described a method by means of which a number of alternate-current curves could be obtained simultaneously with the aid of a single contact-maker. It consisted of passing a current from a battery of cells through the revolving contact apparatus and also through the primary coils of a series of dynamometers. The currents in the secondary coils of these instruments were caused by the voltages or currents which were being analysed. For every position of the contact-maker, corresponding with a definite instant of the period, the readings of the dynamometers were taken and plotted so as to obtain simultaneous curves of voltage or current. This method seemed admirably adapted to the purpose for which it was intended, although apparently requiring special dynamometers, and being subject to the defect that the contact apparatus had to be made capable of carrying an appreciable electrical current. In all methods of determining these curves hitherto used, the contact-maker has been used merely for completing a condenser circuit, or in such a way that practically no current passed at the instant of contact; and so much depends upon the certainty with which the contact piece performs its duty, that any disturbing element, such as the passage of a strong momentary current, should be avoided if possible.

Messrs. J. E. Moore and E. M. Tingley have, however, recently tried this method with promising results; and in the *Electrical World* of June 4 will be found some interesting alternate-current curves obtained by them. The dynamometers used were of the ordinary Siemens pattern, but the current across the contact piece was only a tenth of an ampere. The curves obtained are of the same general type as those obtained by other methods, and already published. For low magnetisations, the current curves differ very little in shape from the voltage curves; but for high magnetisation the current rises very slowly at first, then mounts quickly to its maximum value, and afterwards falls with great rapidity to zero again.

A well-established principle of patent law was explained by Lord Abinger when he said that because all mankind have

Digitized by Google

been accustomed to eat soup with a spoon a man could not take out a patent for eating peas with a spoon; and similarly the method of testing transformers which has been devised by Dr. SUMPNER, and which is fully described by him in the present issue, is confessedly based upon Dr. J. HOPKINSON'S well-known method of testing dynamos, but is none the less important even if it is not novel in principle. It is indeed rather surprising that Dr. HOPKINSON himself, in carrying out the very elaborate test of a transformer which is described in another column, did not use this adaptation of his own method. We must repeat the confession, already made in this journal, that we are getting rather tired of transformer testing; but it still seems to have a wonderful fascination, and we have by no means heard the last of it. Transformers, their design and behaviour, have been revelled in from a mathematical point of view by many writers who seldom see or care to see an actual example. Absurd bundles of iron and copper have, on the other hand, been built by manufacturers who were innocent of any mathematical knowledge whatever.

THE development and perfecting of the alternate-current transformer seems likely to depend, not on its practical working, for it is impossible to tell whether a transformer is working in a creditable manner when it is simply engaged on the ordinary work of electric lighting, but on the art of testing. Those types which pass the tests best will take the first place, unless, indeed, cheapness of construction or economy of material are found to be of greater importance than those electrical losses which it is the object of testing to discover and to measure. Just as Dr. HOPKINSON coupled two nearly identical dynamos on one shaft and allowed them both to work at full load opposing each other on the same circuit, and supplied a small amount of power from an external source to make up for the losses, so Dr. SUMPNER proposes to arrange two transformers, and to supply, and thus to measure, by means of a small third transformer, the power lost in the large ones.

THE Paper read by Mr. WILLIAMS at the last meeting of the Physical Society forms a most important contribution to the theory of dimensions. Professor THOMPSON'S idea that a directional quantity must be represented by a unit which is itself of the nature of a vector, has been followed up with marked success. The old view, which many have more or less unconsciously held, that the dimensions of a physical quantity can be completely represented by reference to the fundamental units of length, mass, and time, seems entirely fallacious, and, indeed, the absurdity of it is sufficiently apparent when we find that the dimensions of most physical quantities are represented in terms of these units by a most extraordinary combination of powers. Professor RÜCKER'S former Paper on the suppressed dimensions of physical quantities seemed to indicate that it is doubtful whether the true dimensions of any quantity are really known.

CAN it be said, for instance, that we are sure of the nature of mechanical force? This is a quantity which, like an electric current, can only be detected by the effects it produces. There is no such thing as a theoretical proof of the law known as the parallelogram of forces. Any so-called proof which can be given is either purely experimental, or depends upon definitions and assumptions which are the result of experiment. If it be assumed that the force acting on a body is measured by the product of its acceleration and its mass, the parallelogram of forces can be proved. But no real proof can be given that the dimensions of a force are those of mass multiplied by acceleration. We cannot, for instance, be sure that the gravitational force between two material bodies depends only on the masses of these bodies and their distance apart; and, as a matter of fact, we know that with electric and magnetic attractions we have to take into account the nature of the medium between the bodies. In determining the dimensions of force we may, in fact, have suppressed some quantity analogous with κ and μ in the electro-magnetic system, and a recognition of which may possibly, in the end, effect a simplification of ideas.

SURELY, if slowly, the views which Mr. OLIVER HEAVISIDE has developed in the pages of *The Electrician* are leavening the scientific world. The latest evidence is to be found in this elaborate Paper of Mr. WILLIAMS. We venture to characterise the Paper as the most important that has been produced before the Physical Society during the current session; not because it announces any new discovery, but because it virtually applies a new weapon for attacking some of the knotty problems of ultimate physics. There is nothing inherently new in the discrimination of physical quantities into vectors and scalars, the former having the property of direction as well as magnitude. But the introduction of vector ideas into the expressions for the "dimensions" of physical quantities has, in Mr. WILLIAMS' hands, certainly thrown some light on the obscure nature of those "suppressed dimensions." Whether the sacred symbol 4π is henceforth to disappear from electrical formulæ by the adoption of OLIVER HEAVISIDE'S "rational" system of units, or whether it remains for a time, Mr. WILLIAMS has done a useful service in pointing out precisely the physical and spatial relations which its presence in those formulæ implies. To the plain man the recurrence of this symbol is an abomination. He would certainly prefer in practice to relegate it to the realm of "suppressed dimensions."

WHEN Mr. TESLA showed a flame in which there was no consumption of material, but, as he put it, merely a transfer of energy, it appeared to be an intense form of the well-known brush discharge at a point, and, like the luminosity of a vacuum tube, seemed to come under the convenient term "electrical discharge," which commits us to nothing. A lightning flash, on the other hand, has been considered by some authorities to consist in the incandescence of the air through which the "discharge" takes place. No one, however, has seen red-hot air, and no one has attempted to explain at what point, if any, air becomes self-luminous. When, however, high-pressure discharges are forms of popular enter-

Digitized by Google

tainment, we get familiarised with the long writhing ribbon-like flames that play between the terminals under several thousands of volts.

PROF. CROOKES has given one of those simple explanations of these flames which are surprising only in that they have not been thought of before. The flame is a true flame, and consists of nitrogen burning in air, that is, combining with the oxygen of the air, and forming nitric acid. Fortunately, the combination of oxygen with nitrogen does not take place with sufficient evolution of heat to maintain the combustion, or, as Prof. CROOKES suggests, the first lightning flash would have fired the air, and deluged the earth with a sea of nitric acid. To make all this nitric acid a good deal of the ocean would be needed, and even then a lot of nitrogen would be left over. We must be thankful that the molecules of oxygen and nitrogen get on so good-humouredly together, and that we escape by the skin of our teeth from this as from other tricks which Nature is within an ace of playing us.

NOWHERE have these long flames been seen to better advantage than at the demonstration of Messrs. SIEMENS BROS. at the Crystal Palace, or those of Messrs. SWINBURNE and Co., who, by-the-bye, have been compelled, in a rather arbitrary way, to stop their experiments, and who very properly declined to remove their stall and exhibit fully a fortnight before the close of the Exhibition, because the space which had been allotted to them was wanted for a concert.

The Westminster Electric Supply Corporation.—The Board of this Company have reduced the standard price of current supplied to 7d. per unit from to-day.

The Cable Companies.—In its last issue our financial contemporary, *The Statist*, had a well-written article drawing the attention of investors to submarine telegraph securities.

Old Students' Association.—On Thursday last week Mrs. Silvanus Thompson held a most successful and largely attended reception in connection with the Old Students' Association.

Brussels.—The tender of the India-Rubber, Gutta-Percha, and Telegraph Works Company, of Silvertown, for the electric lighting of Brussels, was definitely sanctioned on Monday by the Conseil Municipal.

The Varley Testimonial.—The meeting called for to-day at 4 p.m. will be held in No. 4 Room, Westminster Palace Hotel, instead of at the offices of the Institution of Electrical Engineers, as previously announced.

The Spanish Telegraphists' Strike.—The strike of Spanish telegraph operators was settled on Friday last, as a result of the mediation of the Minister of the Colonies. Telegraphic communication is now restored.

Personal.—Prof. George Forbes has returned from the United States, and has been appointed consulting electrical engineer to the Cataract Construction Company, who are undertaking the utilisation of the water-power of the Niagara Falls.

Dundee.—At a recent meeting of the Dundee Gas Commissioners it was resolved to borrow, subject to the approval of the Secretary for Scotland, a sum of £20,000, for the purpose of erecting and equipping the proposed electric lighting works.

High-Speed Electric Traction.—M. Van den Kerchove, of Ghent, is in negotiation with the Belgian Government for permission to lay down an electric rapid transit line between Brussels and Antwerp. M. Van den Kerchove proposes a ten minutes' service, and to do the trip of 27 miles in 25 minutes.

The Institution of Electrical Engineers' Conversazione.—We are requested to state that owing to the limited cloak-room accommodation at the Royal Institute of Painters in Water Colours, it would be well if soft hats or opera hats (rather than ordinary tall hats) were worn in coming to the Conversazione this evening.

Proposed Electrical Exhibition in Milan.—A meeting has been recently held at Milan, says *Industries*, by the principal engineers and manufacturers to consider whether it would be advisable to hold an Electrical Exhibition in that city; and it was decided to hold one in 1894. A commission of five members was appointed to draw up the necessary programme.

City and Guilds of London Institute.—The entrance examination for the Central Institution will be held on September 19-22nd, and for the day department of the Finsbury Technical College on September 27th. The new session of the Central Institution commences on September 28th, and that of the Finsbury Technical College on October 4th. For further particulars see our advertisement columns.

"The Electrician" Annual Dinner.—The annual dinner of gentlemen associated with *The Electrician* was held at the Criterion Restaurant, on Monday last, under the chairmanship of Sir James Anderson. The party numbered over 50, and amongst the visitors were Sir Eyre M. Shaw, Sir Albert Cappel, M. Despecher, Mr. G. Ward, Dr. J. A. Fleming, Prof. J. A. Ewing, Capt. Davies, Mr. W. O. Smith, and other gentlemen well known in the electrical profession.

New South Wales and the Chicago Exhibition.—The colony of New South Wales is said to be dissatisfied with the arrangements made for the exhibition of its mineral and other products at the Chicago Exhibition. It is declared on behalf of the Colonial Government that as the original conditions have been ignored by the Executive at Chicago, the colony will, unless arrangements are made by which the products can be exhibited in one court, withdraw from the Exhibition altogether.

Accumulator Efficiency.—M. Vitte has sent the following figures to *L'Industrie Electrique* with regard to the mean monthly efficiency of a battery of Tudor cells installed at the electrical works of the Lyons Gas Company. From March 5 to March 31 last 2,828 kilowatt-hours were put into the battery and 2,477 were taken out, which means an efficiency of 87·5 per cent. The battery in question has a capacity of 150 kilowatt-hours, and its average daily output is about two-thirds of this.

Obituary.—We regret to record the death, at his house in London, on the 26th ult., at the age of 50, of Mr. William Payton, Secretary of the Globe Telegraph and Trust and West African Telegraph Companies. Sir John Pender, as well as the other Directors of the Cable Companies, had a high appreciation of the deceased gentleman's abilities, and reposed great confidence in him both in his official and private capacities; while his generous and kindly disposition endeared him to the large number of friends in all parts of the world, by whom his loss will be deeply regretted.

"Total Light."—The *Journal of Gas Lighting* comments on the "animated little controversy" which has been going on in *Industries* on the subject of "candle-feet," and the "curious result that a candle gives a total light of 4π, or $12\frac{1}{2}$ candles." "It will be a mercy," says our contemporary, "if the electricians do not get hold of this pleasing mathematical convention, and hoodwink unsuspecting local authorities with it One can, indeed, hardly contemplate with equanimity the result of bringing such a magnificent specimen of the 'unearned (mathematical) increment' within arm's length of the Brush Company."

The Belt Line Tunnel.—While the minor details of the Belt Line tunnel at Baltimore have not been decided upon, says the *Electrical World*, the essential features of the installation are now known. The 80-ton locomotives will be capable of developing 1,200 H.P. each. There will be four driving axles, on each of which will be keyed the armature of a 300 H.P. motor. The conductors will be either a third rail of iron or some sort of a large copper tube laid above the ties and thoroughly insulated. The potential is to be 500 volts. The power station will probably have a capacity of 3,000 H.P. There will be four compound Corliss engines of about

Digitized by Google

750 H.P., each belted to or directly coupled to the generators, no counter shaft being employed.

Electricity in Mining.—The electric plant at the Virginius mine is an illustration of the great benefits to Western mining interests which have been brought about by some applications of electricity as a motive power for mining machinery. An American paper says:—"The Virginius is situated on Mount Aniffles, near Ouray, Colo., at an altitude of some 12,500ft. It formerly cost $15 per ton for coal with which to operate this mine, as all fuel had to be transported up the mountain on burros. The cost of coal reached $100 per day, or an annual aggregate expense of $36,000 for fuel alone. Every cent of this heavy running expense is now saved to the mine-owners. The new operating force of the Virginius is water-power, transmitted by dynamos located at Red Canyon Creek, four miles from the mine."

Central Station Lightning Arresters.—The precautions which American central-station engineers find it necessary to take against lightning is one of those little things which remind us of the different conditions under which central-station work is carried out in England and in the States. Thus, at Springfield, Ill., the lightning arresters which were formerly placed in the top of the tower from which the circuits were distributed have recently, says the *Electrical Engineer* of New York, been changed and lowered in the tower to a level with the ceiling of the dynamo-room, and pipes are run so that in case of an arc from lightning they can be surrounded with live steam. This precaution was taken from experience gained from a recent storm, when an arc formed by the coming in of the lightning upon the arresters almost resulted in a disastrous fire.

Berlin.—The Berliner Electricitätswerke intend from the 1st January next to make several concessions to their customers, the most important of which is that consumers will be allowed to supply their own lamps. Consumers who undertake the supply and care of the lamps themselves will then pay for each arc lamp a yearly sum of 15 marks, instead of 30 marks as formerly, and for each incandescent lamp two marks, instead of five marks as formerly. The calculation of the price for electricity consumed will be based, as hitherto, on the rate of 3·6 pfennigs per lamp hour. Furthermore, consumers will be permitted to run electric power plants and accumulators of all kinds from the Company's mains, so long as the same meet the rules and regulations prescribed by the Company in this regard.

Electrical Bills in Parliament.—The Royal assent has been given to the following electrical Bills:—Telegraphs, Electric Lighting Orders Confirmation (No. 5), Central London Railway, and Great Northern and City Railway. The following Bills are suspended:—Baker-street and Waterloo Railway (waiting for third reading in the Second House), Blackpool Improvement (read the second time in the First House), City and South London Railway (Islington extension) (read the second time in the First House), Hampstead, St. Pancras, and Charing Cross Railway (read the second time in the First House), London County Council (Subways) Bill (waiting for report from the Select Committee in the Second House), National Telephone Company's Bill (read the first time after introduction), Waterloo and City Railway (read the second time in the First House).

Bradford Tramways.—Our readers will be glad to hear that the experiment undertaken by Messrs. Easton and Anderson in conjunction with Mr. M. Holroyd Smith, on behalf of the Bradford Corporation, to demonstrate the efficiency of electric energy in propelling tramcars up steep hills, have been brought to a successful conclusion, and arrangements are now being made for the construction and equipment of two miles of line where the average rise in the total length is 1 in 24, the road in many places being as steep as 1 in 13·3. The Corporation has consented to allow the temporary overhead conductors used for the demonstration to remain in position for another fortnight in order that gentlemen from other towns interested in tramways may witness the running of the cars. Should any of our readers desire to personally inspect the tramway and its working they may, on application to the London office of Messrs. Easton and Anderson (Limited), 3, Whitehall-place, S.W., be furnished with the necessary permits.

The Severe Thunderstorms.—The violent thunderstorm which occurred in the Metropolis on Tuesday and Wednesday last was also felt very severely over the midland, southern, and eastern portions of England. Amongst the many accidents caused by lightning was that at a house in Lordship-road, Stoke Newington, which was set on fire. Considerable damage was done at Richmond; and amongst other places more or less injured by lightning was Moor Hall, in Essex, a farmhouse at West Grinstead, a technical school at Bickley, a house at Brasted (Kent); whilst animals suffered somewhat severely from lightning at Luton, St. Alban's, Hatfield, Saffron Walden (Essex), and Harefield. A correspondent, Mr. W. B. Clarke, writes to us under the date of June 28th, as follows:—"No doubt the storm of to-night has been the subject of numerous communications to you, but I thought I would mention one flash in particular which occurred just before nine o'clock. This was a flash from sky to earth of zig-zag path, which left a stream of sparks in its train. This was very noticeable, and was seen by several. I cannot call to mind having before seen such a noticeable stream of sparks following a flash."

Electric Railways of the Future.—Mr. Westinghouse, says *Industries*, is reported to have given it as his opinion that the ordinary locomotive will never be replaced by its electric rival. There is, however, a growing idea that the ordinary railway will soon be run from stationary power stations. Electric underground railways will, of course, come into use, as they avoid the ventilation difficulty, which gives them an advantage at once; but in ordinary railway working the smoke and steam from the engine are of little importance. It is generally taken for granted that electric railways will have a much higher efficiency. It must be remenbered, however, that the locomotive is one of the best examples of modern engineering, and that, in spite of the difficulties of the case, it is a very efficient steam engine. The advantage of the stationary engine over the locomotive can hardly be great enough to allow a margin for the losses by conversion of mechanical into electrical power, by transmission, and by reconversion back to mechanical power. The electrical difficulties are also serious. The somewhat barbarous practice of wasting most of the available pressure on resistances at starting will, of course, be abandoned before long, but even then there seems little reason for thinking that the steam locomotive is doomed. The ideas of making electrical automatic block systems are too far-fetched to be of much importance. A tenth of the expense involved would make the present railway systems automatically safe—that is, unless something went wrong with the automatic gear.

The Proposed Electric Lighting of the Thames Embankment.—At the last meeting of the London County Council, the Highways Committee reported that their attention had been directed to the defective lighting of the Victoria Embankment. With regard to a supply of electrical energy, three courses appeared to be open for adoption—viz. (*a*) to obtain the supply from a company; (*b*) for the Council to lay the mains and provide and fix the lamps and then to obtain the supply from a company; and (*c*) for the Council to light the Embankment by means of an independent installation. The third course appeared to be the proper one for the Council to take. The Committee proposed that lamps of from 1,000 to 1,200 c.p. should be placed in the centre of the road, at about 50 yards from each other. About 50 of these lamps would be required for the carriage-way. The generating plant might conveniently be placed upon the land belonging to the Council under the Charing-cross railway bridge. The capital expenditure, if the above arrangement were adopted, would probably not exceed £10,000; while the cost of maintenance, including depreciation, repair, and interest on capital, and also providing amply for labour, would probably not exceed £2,000 per annum. After some discussion, the recommendation of the Committee was agreed to, with the following addition:—"And that the Highways Committee do also confer with the Bridges Committee and the Parks Committee respectively, and report whether the plant can be established on a sufficient scale to enable Westminster and Waterloo bridges and the Embankment gardens to be lighted from the same source."

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 165.*)

13. Joint in Core.—Before the work of jointing and splicing is commenced the end on the new piece of cable to be joined on is brought up into position for paying out, so that everything will be ready to pay out as soon as the splice is completed. It is not usual to fit repairing vessels with a separate brake gear aft for paying out as in the large cable-laying steamers, the spare drum and brake on the picking-up gear being available for this purpose. As these are also under steam control when required they further constitute a duplicate set of gear for grappling or picking up; but for paying out the drum is thrown out of gear with the engine, and controlled entirely by the brake.

In the tank from which cable is to be payed out, the end is passed up through the crinoline, and out through the eye above the tank, thence forward to the jockey pulley and drum, round which it is wound four or five times. If it is intended to pay out from the bows the end is taken further forward into position under dynamometer pulley, and then doubled back for splicing; but if paying out is to be done over the stern, the end is taken aft, passed under pulley of dynamometer at that end of ship, over stern sheave, round outside ship to bows, and back inboard again over one of bow sheaves, where joint and splice are made. Arranged in this manner the cable will at once

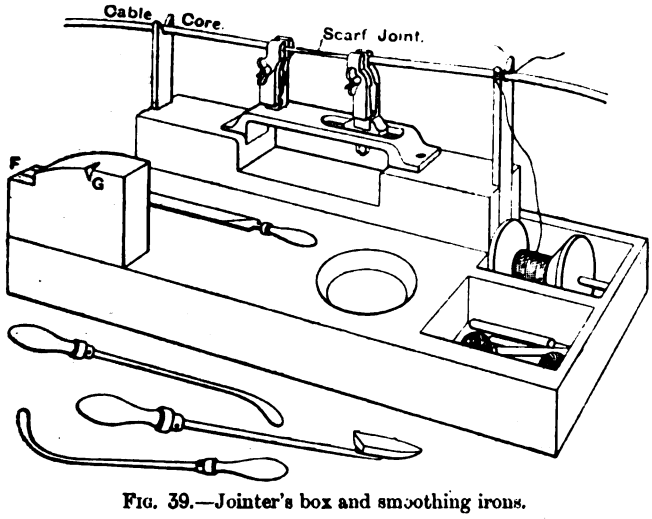

FIG. 39.—Jointer's box and smoothing irons.

take its proper place for paying out over the stern as soon as the finished splice is dropped overboard from the bows. It is now, however, the general practice in repairing work to pay out over the bows, this being most convenient for the short lengths of cable dealt with.

The cable having been got into position, the two ends are brought up together for jointing. On one end, which we will call the left end for distinction, the sheathing wires are unlaid for a length of about 90ft., exposing the same length of core. About 30ft. of core is then cut away, and the remaining end prepared for jointing. On the other end—the right end—the sheathing wires are unlaid for about 75ft., and 60ft. of core cut away, the remaining end being likewise prepared for jointing. To prepare for jointing the insulation is stripped off the end with a sharp knife to a distance of 3½in. or 4in., care being taken not to nick the wires with the knife. The strand is then opened out, each of the seven wires being scraped and cleaned bright with emery cloth, and then with a pair of pliers the whole twisted back again into a strand as before. The ends are then filed down taper on one side, as shown in Fig. 41, for a scarf joint, so that the ends when laid together exactly fit, and make no increase in the size of the conductor. On the jointer's box, illustrated in Fig. 39, there is a block of wood on the left side, in which is cut a niche G. This niche answers the purpose of a gauge to assist in filing both ends equally to the same taper. The end is laid in the niche and filed away till flush with the block, making the tapered part about an inch in length.

The jointer's box is also fitted with two upright hand vices or clamps, as shown, in which the ends are held together while jointing. But before clamping the ends thus, they are separately soldered over. For this purpose the soldering bit, spirit lamp and hood, shown in Fig. 40, are used. With a hood of this kind over the lamp a good draught of air passes through the small holes and out at the top, while the flame itself cannot be blown about by the wind. The soldering bit is also held over the hottest part of the flame, in a hole cut in the hood for the purpose. Either powdered resin or Baker's fluid is used as

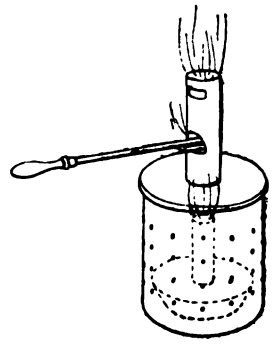

FIG. 40.—Soldering iron, lamp, and hood.

a flux. Sometimes the wire is soldered first, before filing the taper end. The ends being soldered, they are next laid in turn on the side of the block at F, and the rough corners left by the solder filed off; after which they are surfaced over with emery cloth. At this stage the ends are solid, fitting truly together, and presenting a bright silvery appearance. They are now held together in the clamps on the jointer's box, which grip the conductors close to where the insulation is cut away. One of these clamps is movable along a slot, so that when the wires are properly held they can be brought close together with a little pressure, by moving up this clamp as required, and then fixing it by screwing up the nut underneath. The joint is now bound round with fine copper binding wire. A length of this wire is unwound from the reel in the jointer's box, rubbed over with emery cloth, and then doubled in three or four like a flat band composed of three or four wires. So held, it is bound tightly round the joint in one direction, say from left to right, and to within a quarter of an inch of the clamps on each side. The whole is

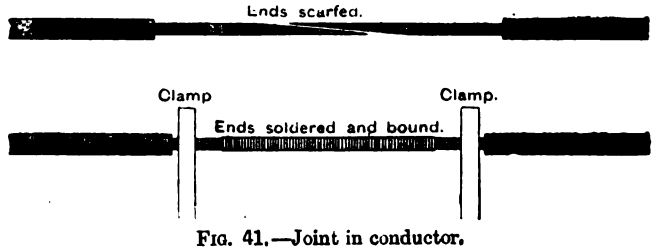

FIG. 41.—Joint in conductor.

then soldered over, the solder running in between the binding wires, and making a neat solid joint. Next, a second wrapping of binding wire is laid on, this time in the opposite direction—right to left—and close up to the clamps on each side. This wrapping is soldered only at the extreme ends for about a quarter of an inch from the clamps, the object being that in case the cable is subsequently fractured at the joint the wire not being soldered will not break with the cable, but open out and maintain continuity. Finally, the ends of the binding wire are snipped off, and a six-inch smooth file run over the soldered parts to take off any projecting points and make the joint perfectly regular all the way along.

So far there will not be found much difficulty in jointing after a little practice in keeping a nice clean tinned end on the bit. There is considerably more practice required in the succeeding operation of making the joint in the insulation, the difficulty being at first to keep all air bubbles excluded from the material while hot, and to finish with the jointed conductor

* All rights reserved.

Digitized by Google

perfectly central in its insulating covering. Should there be any air bubbles imprisoned in the joint they are sure to be the cause of ruptures in the insulation sooner or later in consequence of the great pressure at the bottom of the sea. This pressure amounts to one ton and a quarter per square inch for every 1,000 fathoms depth; and when the cable is sunk and subject to this pressure any places where air is imprisoned are burst open and cause serious faults.

The soldering fluid is first cleaned off the joint by rubbing with a clean bit of rag soaked in wood naphtha, and after drying it the first coat of Chatterton's compound is laid on. One end of a stick of this compound is heated in the spirit lamp flame, care being taken not to keep it in the flame long enough to burn, or there will be trouble from air-holes. The bare part of the joint is also heated very slightly to receive the coat. The stick of compound is then worked along over the joint as well as possible to cover every part, and is followed up by a smoothing iron. This is a smooth iron tool, curved at the end (Fig. 39), which, when heated and worked over the coating of compound, spreads it out in any desired way; thus where the compound is too heavily laid on in places it can be worked down into cavities so as to make it everywhere of the same depth. Any imprisoned air is worked out by this tool, and the coating finally smoothed round evenly by the finger and thumb, first wetted, so as not to adhere to the material. The gutta-percha covering of the core on each side of the joint is now dealt with, the spirit flame being held underneath while the core is turned round backwards and forwards. The ends are then drawn together till they are about ½in. apart, and one end is drawn down to a point, while the other is drawn over it (Fig 41 A), thus completely enveloping the joint in the same material as

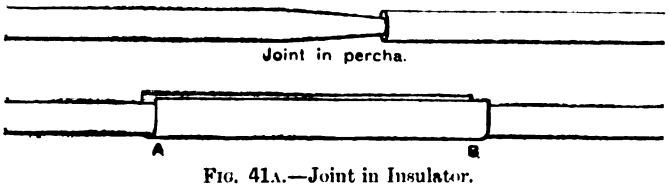

FIG. 41A.—Joint in Insulator.

the conductors on each side. The end so left is further heated and smoothed down. A second layer of compound is now spread over the percha, precisely as before. Some sheet gutta-percha is now taken, and a square piece about 8in. wide cut off. This is heated over the flame, and a strip cut off about 1½in. wide, which is then taken, and one end laid against the core underneath at A (Fig. 41 A), the other end hanging down. From this point the strip is pressed upwards against the core by the fingers working along from A to B, and is then heated again and pressed all round the core till the ends meet at the top, as in the figure. The reason for this careful procedure is to make sure there are no air bubbles imprisoned by commencing at one end and squeezing the strip against the core in every part till the whole is covered. When completely pressed all round, the two sides of the strip stick up close together, and are nipped together by the finger and thumb all along, so as to form a seam. The seam is then cropped close to the core with a pair of scissors, and the ends, which now butt, squeezed together. This coat is followed by a similar one put on in the same way, but with the full part of the strip over the seam of the last. The joint is then completed by working down smooth the ends of these strips at A and B, so as to taper off gradually on to the core on either side. A well-made joint is, when finished, from 6in. to 9in. long, and not much larger in diameter than the adjacent core. The beginner should experiment on short lengths of core, and test his joint by comparing its insulation with a few feet of perfect core by Clark's accumulation method. Then, if sound electrically, he should slice off half of the insulating covering with a sharp knife, so as to lay the joint bare along one side, and notice how near he has got the joint in the centre of the insulating covering. To get the joint central a good deal depends upon working the hands evenly over every part of the coatings as they are put on.

Before anything more can be done the joint must be thoroughly cooled, and for this purpose it is held down in a gutta-percha tray (Fig. 42) containing either a diluted mixture of muriate of ammonia and saltpetre, or a few lumps of ice in water. The proportions of this cooling mixture are given in Munro and Jamieson's "Pocket Book of Electrical Rules and Tables" as five parts of muriate of ammonia to five parts of saltpetre and 16 parts of water. The joint is held down in the cooling mixture by two hooks at the bottom of the tray, and remains in for 15 or 20 minutes. The tray is entirely of gutta-percha and provided with four lugs for suspending, thus thoroughly insulating it for use during tests of joints in short lengths spliced up on board.

Meanwhile the further end of the new piece of cable in tank (on the near end of which the joint has just been made) is connected to the testing-room, and remains so connected, in order to test the cable as it is payed out, and communicate occasionally with the shore. From this end, when the joint is cool, a test is taken through the united cables, the end on

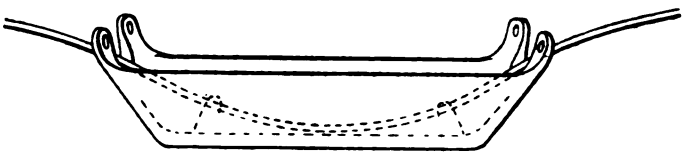

FIG. 42.—Joint Cooling Tray.

shore being free. The insulation of the seaward end, and that of the new piece spliced on being known, it is easily calculated what the two jointed together ought to give; and if the joint is not perfect the resultant insulation will be lower than this. But jointers very rarely fail to make a perfect joint, having served their time in the factory, where joints occur on every two miles of core manufactured, and being chosen as reliable men for sea work.

Preparations are now made for splicing the sheathing wires. The cable is stretched fairly taut, and at a convenient height for the men to work on it as they stand against it. As mentioned above, there is a considerable length operated on—about 90 feet—and stoppers are put on at this distance apart, by which to hold the cable in position while splicing. Messrs. Johnson and Phillips have introduced for this purpose the automatic stopper, shown in Fig. 43. The two jaws A A, which are hollowed out on the inside, and burred here and

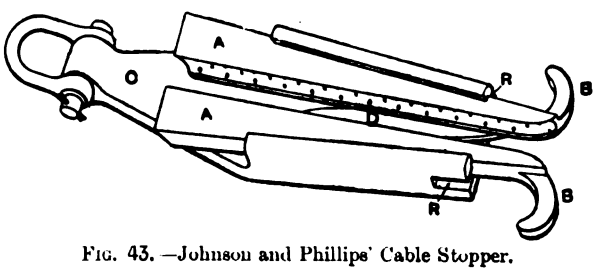

FIG. 43.—Johnson and Phillips' Cable Stopper.

there to grip the cable, slide longitudinally along the bed C between taper guides. The jaws are kept apart by the curved spring D, and if moved to the left towards the shackle, open to receive the cable. When tightened up from the shackle, the jaws close, gripping the cable.

(*To be continued.*)

Balata and Rubber in Guiana.—According to Mr. Consul H. Wyndham, of Paramaribo, the Balata industry, which has only lately become of any importance in Dutch Guiana, will probably grow. In British Guiana the export of "balata," which is attaining considerable importance, will, it is believed, be very productive for a time only, as there is no forest conservancy law in the colony, and parties who are granted tracts of land for the exportation of this product are uncontrolled in their method of drawing the milk, which results in trees being totally destroyed to get the greatest amount of milk by the most inexpensive and quickest method.

THE USE OF WATER-POWER FOR ELECTRICAL PURPOSES.

BY NORMAN F. WILSON.

(*Concluded from page 194.*)

Mixed Flow Turbines.

These turbines are a combination of the inward and axial flow types. The water enters the wheel at the circumference, but instead of leaving at the centre it is brought round by a curve in the buckets, and leaves in a direction parallel with the shaft. Turbines of this type are mainly used and manufactured in America, but they are now becoming more common in Great Britain. Some of them give a very good efficiency and are most serviceable motors, but others are designed with a view to cheapness rather than to reliable and economical working, although the most extravagant promises are made. One of the peculiarities of most of these wheels is their small diameter and great width as compared with the inward and axial flow turbines

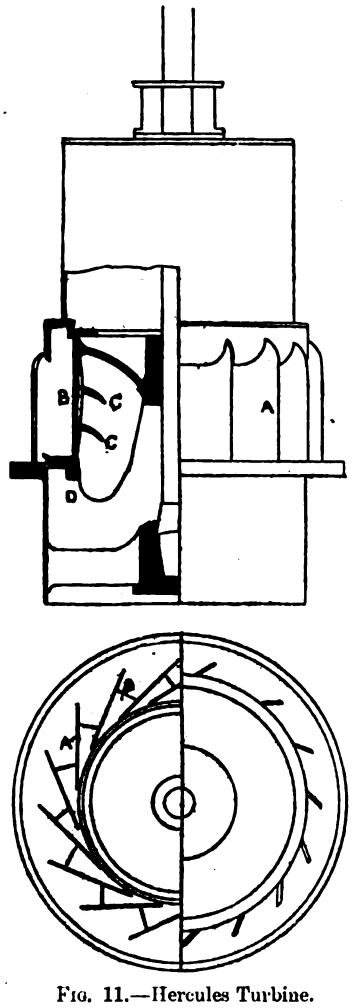

FIG. 11.—Hercules Turbine.

manufactured in England and on the Continent. These turbines are usually designed to work on low falls with a large quantity of water. Under these circumstances the fact of having a wheel small in diameter, making a greater number of revolutions per minute than most others, is often a distinct advantage for electrical work, as the speed of the line shaft is higher. Turbines of this type are not, as a rule, placed on falls higher than 40 or 60ft.

The Hercules and Victor turbines both give good efficiencies, and hold a leading position in the United States; we shall, therefore, take them as illustrations of this type. The water enters all round and is deflected by the hood in the bottom of the buckets, so that it leaves in a direction at right angles to that which it took on entering. Fig. 11 is a general view (part section and part elevation) of the Hercules turbine. Around the wheel is the circular guide-blade chamber, through which the water enters. When it is desired to work below the full power the annular sluice, B, which fits between the guide-blade, is lowered. The efficiency at part gate is good, as the small tongues of metal, C C, which are cast on to the buckets, practically shut the water off from the upper part of the wheel. The wheel then works as if it were designed for the smaller quantity, the upper part being full of comparatively still water. The water joint with the guide-blade chamber is formed at B by a ring which holds all the buckets firmly together. The guide-blade chamber rests on a short suction tube, on which is cast a footstep for carrying the shaft. These wheels are usually fixed at the bottom of the fall, but they can be placed on a horizontal shaft and work by suction if the situation render it desirable to do so.

The wheel of the Victor turbine is somewhat similar in design, but the method of regulating the guide-blades is quite different. The guide-blades are stationary, as before; but instead of the circular sluice or register gate being raised or lowered according to the supply, it is given a horizontal sliding motion by means of a spur pinion and sector, thus lessening the width of the guide passages instead of their depth. Victor turbines are frequently placed on a horizontal shaft, especially when they are used for driving dynamos. Since there is always a certain amount of end-thrust with mixed flow-wheels, it has been found most advantageous to place them in pairs back to back, as they then counterbalance one another. The difficulty with end-thrust is not, however, insuperable, and single turbines of this type work by suction very satisfactorily.

Tangent Turbines.

The essential difference between tangent turbines and the others which we have described lies in the fact that the water

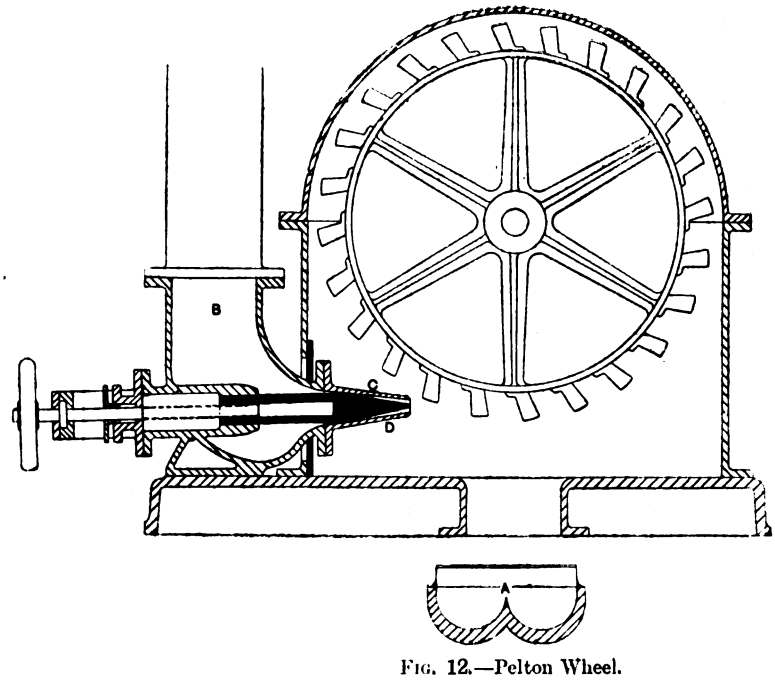

FIG. 12.—Pelton Wheel.

enters and leaves the buckets of the wheel in the same direction, instead of passing through them, as it does in all the other types. Instead of guide-blades, the water is directed against the wheel by one or more nozzles.

One or other of the four types of turbine already dealt with is applicable to almost every situation when water-power is available; but when the fall is very high the expenses of manufacture are often heavy, as the wheels have usually to be large in diameter, and the casings have to be of great strength and well stayed in order to withstand the pressure. Hence a demand has sprung up for an inexpensive turbine, which can be worked under a high fall at a comparatively small number of revolutions per minute.

Of all the turbines designed to meet these requirements the Pelton wheel (Fig. 12) has proved the most satisfactory; the cost is not great and the efficiency is good. In the Pelton wheel illustrated the supply pipe B terminates in a taper piece,

Digitized by Google

to which the nozzle D is attached. This nozzle can be easily removed, and another of a different size substituted when desired. When the wheel is large, the pipe B may be extended so that two or three nozzles can be fixed to it. The gun-metal plug C screws into the nozzle when the wheel is not working. In the enlarged view of the bucket it will be seen that it is divided in the centre by the edge A. This edge separates the jet into two equal portions, one of which sweeps round each side of the bucket before leaving it. The wheel is shown mounted on a bed-plate, with a cast-iron cover over it to keep the water from splashing out.

Water Pressure Reducing Valve.

Considerable difficulty has often been experienced in working turbines on town mains owing to the pressure varying when more or less water is drawn off for other purposes. The

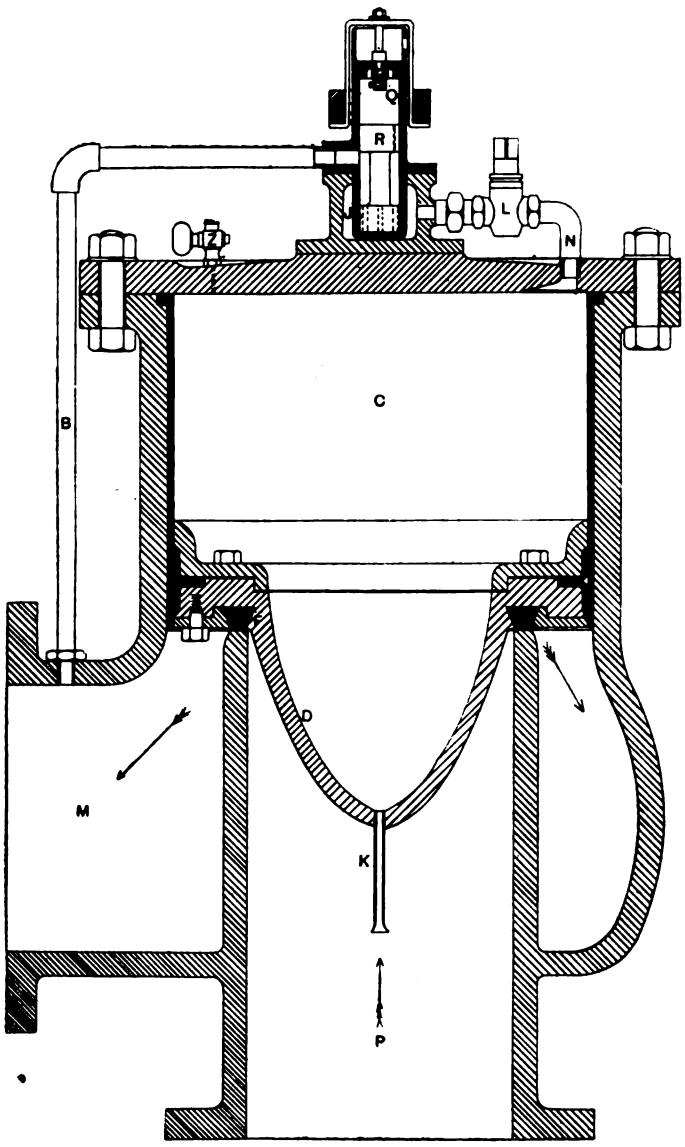

FIG. 13.—Reducing Valve.

turbine, of course, has to be designed for the medium pressure; and therefore, when the pressure rises, it begins to race, and may do a lot of damage to the dynamo or other machinery it is driving unless an attendant be constantly at hand. To obviate this difficulty Messrs. I. Braithwaite and Son, of Kendal, have brought out a reducing valve, Fig. 13, to be placed between the turbine and the supply main. The valve is weighted and designed to maintain a uniform pressure in the turbine case, no matter how much this may be exceeded in the pipes. The flange of the inlet pipe P is attached to the high-pressure main, and that of the outlet M to the turbine. The water passes in the direction indicated by the arrows, from P to M, and thence into the turbine. The piston D is provided with an india-rubber ring, which makes a water-tight joint when it is down. The area of the top of the piston D is twice that of the pipe P, and as the space C, above the piston D, is connected with P through K, the pressure in C would always be the same as in P, were it not that the water can get through the pipe N, and through the regulator and pipe B to M more quickly than it can come in through K. But it must be noted that the pressure from M, acting below a brass piston in the regulator, will raise the piston whenever the water contained below it has pressure enough to raise the weighted safety valve Q. (The water has access to the chamber above it by the very small hole R). As the brass piston rises it closes the holes J J, and presently the passages, which were originally in the aggregate larger than K, become less than K. The pressure in C then increases, and pushes the piston D down, thereby throttling the water, and reducing the pressure in M until it can no longer lift the safety valve Q. If the cock L be shut, the full pressure from the supply is immediately realised in the space C, and the valve is at once closed without the labour usual in shutting a large valve under high pressure. The pressure on M is regulated by adjusting the annular cast-iron weights on the safety valve Q. By the use of such a valve as this it is possible to run dynamos direct on to the circuit without the risk of the lamps being burnt out. When the reducing valve is at work with the ordinary pressure there will be a reduction of the available head equal to about 5 per cent. of the total. When the pressure rises there will be no more loss than with an ordinary valve, since the water would have to be "wire-drawn" in any case. The slight loss in efficiency is, however, amply compensated by the regularity in the speed of the turbine.

THE ST. JAMES' AND PALL MALL COMPANY'S MAINS.

The following correspondence has been addressed to us for publication:—

SIR: I beg herewith to enclose you copies of correspondence which has passed between my Company and the Board of Trade on the subject of certain damage to a gas meter, &c., and alleged to have been caused by a leakage of electricity. As the letter of the Gas Company to the Board of Trade was published and commented on by the gas journals before the matter was brought to the notice of my Company, I should esteem it a favour if, in the interests of the industry, you would give prominence to the matter in your journal.—Yours, &c.,

F. J. WALKER, General Manager and Secretary.

The St. James' and Pall Mall Electric Light Company (Limited),
Mason's-yard, Duke-street, St. James', S.W.,
June 29, 1892.

Board of Trade (Railway Department),
London, S.W., May 19, 1892.

ST. JAMES' ELECTRIC LIGHTING ORDER, 1890.

SIR: I am directed by the Board of Trade to transmit to you, for any observations which your Company may desire to offer, the accompanying copy of a letter which they have received from the Gas Light and Coke Company with regard to an alleged case of damage arising from an escape of electric current.

I am, Sir, your obedient servant,
(Signed) R. GIFFEN.

The Secretary the St. James' and Pall Mall Electric Light Company (Limited).

The Gas Light and Coke Company, Horseferry-road,
Westminster, S.W., May 4, 1892.

SIR: The Directors instruct me to enclose for your perusal the accompanying copy report of their distributing engineer to another case of damage arising from an escape of electric current.

I am, &c.,
(Signed) J. O. PHILLIPS,
Secretary and General Manager.

The Secretary Board of Trade.

[COPY.]

J. O. Phillips, Esq.

DEAR SIR: I have another case of damage to a meter and fittings by electric current in the district of the St. James' and Pall Mall Electric Lighting Company, viz., at 56, Pall Mall. We have a ten-light check meter fixed at the top of w.c. in bath-room on second floor, near to a small cistern, the water supply pipe of which touches the back of meter, and there are electric fittings near the meter. The gas is used for heating purposes only, and is now, by request of consumer, temporarily dispensed with.

Digitized by Google

On the 25th ult. the occupier was startled by the noise of an explosion. The housekeeper saw smoke in the passage, and, noticing a smell of gas, at once turned the tap off at the meter. Meter and fittings are damaged, likewise the coruice and ceiling. Apparently there was a small escape of gas on consumer's fittings, and this was evidently ignited by the electric current. Our inspector informs me that he subsequently saw electricity issuing, in the form of a blue spark an inch long, from the electrical fittings at the point in question. The ignited gas melted the solder on the top of the meter, and also the lead inlet pipe.

I cannot too forcibly call attention to the dangers these electric wires present to our fittings. They arise in such a variety of ways hitherto unsuspected by electrical engineers and also, I apprehend, by insurance companies. The risk of fire being attributed to us, when all evidence of the real cause may be effaced, is a very grave one to my mind.

I am, &c.,
(Signed) G. F. L. FOULGER,
Distributing engineer.

The Gas Light and Coke Company, 146, Goswell-road, E.C.,
May 3, 1892.

Both gas and electric fittings work was executed by Messrs. Liberty and Co. of Regent-street.

The Assistant Secretary (Railway Department),
Board of Trade, London, S.W., May 31st.

ST. JAMES' ELECTRIC LIGHTING ORDER, 1890.

SIR: I beg to acknowledge receipt of your letter of the 19th inst., enclosing to my Company a copy of a letter received by the Board of Trade from the Gas Light and Coke Company (Limited), on the subject of an alleged case of damage arising from a leakage of electric current.

On receipt of your letter inquiry was made by this Company, and the facts of the case were found to be as follows:—The gas meter in question was placed on the top of a w.c. in the bath-room of a set of chambers at No. 56, Pall-mall, and was used to register the supply of gas to a stove in the sitting-room, the chambers being lighted throughout by electricity. The supply terminals of my Company with the main meter are situated in the basement of the house, and from this point the landlord's distributing wires are carried through the house for the supply of various sets of chambers. Although the fittings on these premises were put up a few years back, and are not of the most modern description, the insulation of the whole of the circuits in the house is in proper condition. We learn from the landlord that at the time of the accident complained of the tenant of the chambers was in his sitting-room, with the gas stove burning, and that he heard a slight report, the stove being extinguished at the same time. No notice of this appears to have been taken for some few minutes, when, on account of a smell of burning, someone went into the bathroom, and found the damage as described. The gas was at once shut off. In the report of the engineer of the Gas Company it is stated, "that there was a small escape of gas on the consumer's fittings, and this was evidently ignited by the electric current. Our inspector informs us that he subsequently saw electricity issuing in the form of a blue spark an inch long from the electrical fittings at the point in question."

We are informed by the landlord that there was known to be a leakage of gas at the junction of one of the pipes to the meter; but we must protest in the strongest terms against the statement that this gas "was evidently ignited by the electric current." With regard to the "blue spark seen at the point in question," the landlord, who was present with the gas inspector at the time, explains to us that this was seen in the sitting-room, where there is fitted an ordinary Edison tumbler switch. With this switch, as with most other forms, it is possible by moving the tumbler slowly across or by removing the metal cover so as to place it across the switch terminals, to somewhat exaggerate the usual spark at a switch on breaking contact. We need make no further comment on this statement made by the Gas Company, which is put forward by them as evidence in support of a charge both rash and ill-considered. Had the leakage of gas been fired by an external spark as described above, the effect of an explosion would have been visible in the room.

As regards the condition of the electric circuits, the whole of the premises were tested *en bloc* for leakage on the 28th ult., in the course of the usual quarterly tests, and were found to be in order. For the purposes of our inquiry an insulation test was made on the 23rd inst. again from the consumer's terminals, and the insulation resistance of the whole of the circuits to "earth" was found to be 1·18 megohms. The electric fittings had not been altered or disturbed in any way. Apparently the damage was caused by firing back from the stove to the gas leak close to the meter, which then continued to burn. We are informed by the landlord that he does not for a moment think of attributing the damage in any way to the electric circuit, and, further, that when the officials of the Gas Company inspected the premises they were accompanied by an expert engaged by them, who declared at the time in his hearing that he could see nothing in the electric light work that would account for the damage, and suggested that it would have been caused by firing back from the gas stove itself, an accident by no means improbable.

I am instructed, therefore, to ask, in view of the uses to which this incident has been put to prejudice the interests of the industry, that an inquiry should be held in the matter. My Company are not aware as to whether Major Cardew has already made an inspection, as in the previous instance; but they would request that an early appointment be made for him to meet Prof. Kennedy, F.R.S., who has kindly consented to act for the Company in this matter. I am further directed to draw the attention of the Board of Trade to the statements contained in the copy of a paper enclosed herewith, and to point out the uses to which every purely gas accident, such as the above, will be put, unless reasonable facilities are afforded to the various electric light companies to be represented at any official inquiry, and to examine into the cause of any damage within something less than four weeks from the time of its occurrence.

I am, Sir, your obedient servant,
(Signed) F. J. WALKER,
General Manager and Secretary.

Board of Trade (Railway Department),
London, S.W., June 21, 1892.

ST. JAMES' ELECTRIC LIGHTING ORDER, 1890.

SIR: With reference to your letter of the 31st ultimo, on the subject of the damage arising from an explosion of gas at No. 56, Pall-mall, alleged to have been caused by a leakage of electric current, and asking that Major Cardew may be instructed to meet Prof. Kennedy, F.R.S., with a view to a joint inquiry into the circumstances attending the explosion, I am directed by the Board of Trade to inform you that Major Cardew has visited the premises in question, and reported that, in his opinion, there was no evidence to establish any connection between the electric supply of your Company and the small explosion of gas in question, and that in these circumstances the Board of Trade are of opinion that no formal inquiry is necessary.

I am, Sir, your obedient servant,
(Signed) COURTNAY BOYLE.

The General Manager and Secretary, St. James' and Pall Mall Electric Light Company (Limited).

ELECTRICITY AT THE ROYAL AGRICULTURAL SHOW AT WARWICK.

A careful inspection of the Royal Agricultural Show at Warwick reveals the fact that as yet "the application of electricity to agriculture does not exist." It is true that in the show yard are a few dynamos, a few lamps running in broad daylight at unknown voltage, a few spasmodic arc lamps demonstrating the irregular motion of a gas engine; but nowhere do we find the electric cow milker, or the electric curd depositor, or the electric seed raiser, all of which will no doubt some day do for agriculture what the electric furnace has done in metallurgy, or the electrolytic bath has done for metal refining. Magnetism—electro magnetism, indeed—makes a little show; this, perhaps, is the precursor of more, in the form of two magnetic separators for extracting iron and steel from bones, oilcake, &c., before putting them into grinding mills or disintegrators. The first machine is that shown by Mr. J. Harrison Carter (Christy Carter patent), and consists of a barrel revolving, having on its exterior surface projecting poles, alternating north and south; on the top of this barrel are fed the materials containing iron, and any iron coming in contact with the poles adheres, and is carried round and dropped into a separate receptacle by the demagnetisation of the magnets by cutting off the current by a commutator. Considerable science is shown by the very successful removal of sparking at the commutator by the proportioning of the coils, and of the solid copper sheathing round the magnets on which they are wound. The machine takes 40 volts amperes to magnetise it, and will deal with about two tons of bones per hour. Its weak point seems to be that if a piece of flat iron, say, happens to fall on the drum with a non-magnetic body in between it and the pole piece, it will not adhere; and one miss renders a machine of this kind useless, as the disintegrating mill is seriously damaged. Another machine, shown by the Hardy Patent Pick Company, of Sheffield (Atkinson Elliott patents), is an improved form of a somewhat similar machine shown last year, and is devised to overcome this objection. It consists of a hollow inclined drum, through which the material is fed. The interior surface presents a series of poles, magnetised through half a revolution in such a manner as to pick up and deposit in a tray any magnetic material. In this machine, as it takes about ten revolutions for any particular piece of material to pass through, and there are ten poles, one hundred chances occur for any piece to be caught. We understand that in many months' use of one of these machines by the Farmers' Company at Hull, no piece of iron has passed through; and pieces of all sizes, from a hair-pin to a hatchet-head, have been extracted. These machines are also used for taking miners' wedges and picks out of coal before grinding for coke-making. This machine takes 100 volts 7 amperes to magnetise it. It was magnetised by a small Goolden dynamo.

Among dynamos shown in connection with gas or oil engines running lights were to be noted a well-finished machine by Newton and Co., Taunton, driven by a Priestman oil engine, the lamps used being 50 c.p. Edison focus lamps; a small dynamo by Holmes, driven by a Trent gas engine; a Tyne dynamo, by Messrs. Scott and Mountain (Limited), driven by a Robey oil engine; a small Kapp dynamo, by Messrs. Johnson and Phillips, driven by a Hornsby-Akroyd oil engine.

We hope next year to see some advances in the direction of applying electricity to agriculture, for certainly in few directions is there so large a scope open,

CLUB LIGHTING.

Political economy is said to be intended only for theoretical study; and economics, according to some authorities, are profitable only in so far as they analyse past history. To apply these sciences to the present is too often misleading, and to attempt by their aid to forecast the future is rarely advantageous. But there are one or two maxims which inspire a confidence as complete as that which is justly placed in OHM's law; and the exceptional cases in which this confidence appears to have been misplaced are so rare that they need hardly be considered. One of these is "the price of a thing is what it will fetch." It may be fatalism or it may be optimism, but it is perfectly certain that this law will hold its own in the long run. "The position of copper" is a favourite theme for financial journals when there is nothing doing in other matters, not even perhaps in the copper market. Truly as this simple law is followed during the rise, continuance, and inevitable collapse of a "ring" or "corner," so surely also does it predict the return to equilibrium of normal price, unless indeed a real monopoly is established. It may at first appear that a monopoly destroys the simplicity of this law, but it really includes the principle of supply and demand, and the special case of monopoly value. The price of a monopoly is theoretically fixed at that which will give the producer the maximum profit.

There have been many grumblings about prices in the electrical industry, and it has been often suggested that the price of dynamos and lamps is too high, and that cable rates and the price of the supply of electrical energy are artificially maintained at a point which is felt to be grievous by the consumer, and therefore unjustifiable. The latest grumble comes from a number of Secretaries of clubs who recently held a meeting at White's to discuss the question of the

Digitized by Google

heavy charges which are being made by the electric lighting companies for the supply of the electric current. The following clubs were represented, all of which use the electric light:—White's, Devonshire, Travellers', Windham, Reform, Orleans, St. Stephen's, Conservative, Brooks's, Junior Army and Navy, Thatched House, National, Oxford and Cambridge, and Prince's. A deputation from the meeting was appointed to wait upon the directors of the companies supplying these clubs, to request that a considerable reduction should be made in the charges, which, it was agreed unanimously, had become most onerous.

It is well known that a club is a most valuable customer to a supply company. Comfort is generally studied, and that implies not only plenty of light, but light arranged in a comfortable manner. It cannot be denied that while electric lamps can be placed in any position whatever, and provided with any kind of shade, it is no easy matter to secure comfort and economy simultaneously; and unless the lamps are arranged with considerable care, a good deal of current is wasted. Besides this waste, which may be avoided, there is the unavoidable length of time during which the light is required. Most of the lamps in a club are in use continuously from dusk until the hour of closing. The average number of hours a day during which a lamp is used in a club is very much greater than in most other establishments; and it is on this, perhaps, rather than on account of the large number of lamps, that clubs are valuable customers. The facility for turning on and extinguishing the lights, which is a feature of so great convenience in domestic lighting, is hardly felt in a club. The main advantage to the members is the coolness, and to the proprietors the cleanliness. The coolness must be looked upon as a luxury, and paid for naturally at a price higher than gas; but the absence of dirt ought to be clearly appreciated, and the saving in cleaning and decoration ought to be distinctly realised. When these two points are considered, the increased cost of electric lighting, even if the convenience be not considered, is not so heavy as appears to be imagined. It is difficult to understand why the charges made to these clubs should have "become most onerous," unless, indeed, it be due to the termination of annual contracts and the introduction of meters. Several very bad bargains were made at first, and the supply companies have been only too eager to terminate them and to fix meters. While contracts have been running there has been no inducement whatever for the managers of clubs to economise in the use of their lights; and careless use of electric light when and where it was not really wanted, has tended no doubt to increase the bills. Sir F. Bramwell has pointed out that the great convenience to which we have already referred, viz., the facilities for turning lamps on or off, really contributes largely, under proper management, to economy; and it is to the careful extinguishing of lamps when not wanted that he attributed the fact that, in his case at any rate, electric light cost very little more than gas had done. Under contracts, this art of economising has not been studied, and hence, no doubt, much waste arises. Prices will be spontaneously lowered, and it is announced that from to-day the Westminster Company have reduced their standard price to 7d. Most companies offer important rebates to large customers, and no doubt further concessions will be granted, especially to such applicants as the Secretaries of important clubs. But as long as electrical energy is found to fetch 7d. per unit, that will be the price for ordinary customers; and unless the supply companies are found to be doing so well that the Board of Trade finds it possible to reduce the maximum price (which they are empowered to do every seven years) anybody who gets a rebate should be thankful for it.

REVIEWS.

The Electromagnet, and Electromagnetic Mechanism. By Silvanus P. Thompson, D.Sc., B.A., F.R.S. (London: E. & F. N. Spon. 1891.)

Although by no means such a weighty contribution to electro-technical literature as that *magnum opus*, the Fourth Edition of "Dynamo-Electric Machinery," the present volume is none the less valuable. Electromagnets and electromagnetic mechanisms have always had a peculiar fascination for the amateur; and bearing this fact in mind, no doubt, the author has adopted throughout an almost popular style. Both the telegraph and the telephone engineer, however, are interested in electromagnetic devices; and the author, therefore, spares no pains in making the laws of electromagnetism plain sailing for them, at the same time that he exposes for the benefit of the student the innumerable fallacies and popular superstitions which have so long encumbered this corner of physical science.

"It is the aim and object of the present work," the preface tells us, "to show how the same considerations which have been applied with such great success to the subject of the design of dynamo-electric machines may be applied to the study of the electromagnet. The theory and practice of the design and construction of electromagnets will thus be placed, once for all, upon a rational basis." We think there can be no gainsaying that the author has attained his object, and that both those who are occupied in the electrical industries, and those who follow science for its own sake, will benefit by a perusal of this work. It is, indeed, a matter of no little congratulation that English men of science of the first rank are still to be found willing to devote their time to the somewhat thankless task of book-making. In ordinary every-day literature one occasionally comes across an author whose style is such as to render his readers almost oblivious to the poverty of his matter. Teutonic writers, on the other hand, have much to say but seldom an attractive style. No scientific writer has, perhaps, ever erred in the former direction; though the name of those who have disheartened their readers by their diffuse verbosity is legion, while those who have succeeded in hitting the golden mean may be counted on one's fingers. We have, indeed, met with perverse individuals who hold that the paths of knowledge may be too smooth, and who prefer an obscure style, since "it makes men think for themselves." It is satisfactory to find that the author of "The Electromagnet" is not in favour of erecting such artificial barriers against the attainment of truth. It is to be regretted, however, that he has allowed the otherwise admirable lucidity of this work to be in some degree marred by constantly ringing the changes on inch and centimetre measure, and by the retention of the direct form of address, as to an audience. National individualism, long use, and the custom of the trade may make "the inch" a necessity in electro-commercial dealings; but, for heaven's sake, do not let us encourage laziness and promote scientific isolation by interspersing $\mathfrak{B}$'s with $B_{\frac{1}{2}}$'s. If English electrical engineers really must have their magnetic inductions in lines per square inch, the $B_{\frac{1}{10}}$s, &c., might, at any rate, be relegated to an appendix. Again, to be suddenly told, as we are on page 205, that we are "smiling" when conscious of having done nothing of the kind, and again, on page 213 and elsewhere, that "the spot of light on the screen is reflected from my galvanometer at the far end of the table," reads somewhat queerly in the middle of a serious volume on electromagnetism. The author also displays a decided liking for new terms. When "grave and reverend seigniors" talk of *quads*, *secohms*, and *henries*, not to mention *permeance*, *remanence*, and *reluctance*, no wonder lesser lights try their "'prentice hands" at *thoms* and *gausses*, and similar scientific slang, until a glossary threatens to become an indispensable adjunct to every electrical publication.

We will conclude our notice with a brief enumeration of the contents. The history of the subject is summarised in the Preface and in Chapter I. The elementary principles and fundamental phenomena of electromagnetism and the magnetic properties of iron are then dealt with. In Chapter IV. the

Digitized by Google

law of the magnetic circuit and the law of traction are gone into at considerable length, and the bearing which they have on various magnetic paradoxes is clearly pointed out. The succeeding section is mainly devoted to a consideration of magnetic leakage, and is followed by chapters on the winding of electromagnets, and on rapid-acting electromagnets. Prof. Thompson is never so happy as when engaged in stamping out heresy, and the law of inverse squares as applied to the pull of an electromagnet on its armature is, we are informed on p. 161, "not proportional to the distance, nor to the square of the distance, nor to the cube, nor to the fourth power, nor to the square root, nor to the three-halfth root, nor to any power of the distance whatever, direct or inverse." . . . Chapter VIII. is devoted to the mechanism known as the coil-and-plunger, all the vagaries of which are shown to be explained by the law of the betterment of the magnetic circuit, and the integration of larger B^2 over a smaller area. Succeeding sections deal with the leading varieties of electromagnetic mechanisms; and the book closes with a long and exceedingly interesting chapter on permanent magnets, the latest researches on the relation between temperature, chemical condition and magnetic property being succinctly set forth.

The Mechanical Engineer's Pocket-Book. By D. K. Clark. (London: Crosby Lockwood and Son. 1892.)

Although we received this book so long ago as December last, we have no apology to make for delaying a review for so long a time, since we have during the past six months constantly used it, at first for trial, and afterwards on account of its real merits, and from this experience can testify to its great value. It is impossible to judge of a book of reference by a glance through its pages, and one cannot sit down and read straight through a book of this kind. If a pocket-book is to please—not everybody, perhaps, but a large number of readers—it is manifestly improbable that any one of them will find that it contains just what he wants and no more. It is better, then, to err a little on the side of versatility, and this is, perhaps, done in the present work. It is preceded by a full and clearly arranged list of contents, and is concluded by a good index. An "introduction to the tables," after the plan of Chambers, is followed by an excellent table, which has for many years been used in Continental books, giving circumferences, circular areas, squares, cubes, square roots and cube roots of any number of diameter, on a single line. The table of logarithms is not easy to use, and should be divided into sets of five lines. The trigonometrical tables are continued straight on from 0° to 90° without the usual confusing retrograde arrangement after 45°. Sines and cosines are given in one table, and tangents and cotangents in another, both going to half degrees. A short table of trigonometrical relations should be added. The weights and measures are very complete—if anything, rather too miscellaneous. A large number of compound and collective tables are given, showing, *e.g.*, 1lb. per lineal yard = 0·7857 ton per mile. The metric tables are very complete, and many compound equivalents are given; such as 1lb. per cubic foot = 16·02 kilos. per cubic metre. An excellent table, No. 86, of specific gravities, is made rather confusing by being arranged alphabetically, gold coming next to glycerine, and palladium to petroleum; but classified tables are given in addition. Weights of a large number of forms of manufactured metal are given, *e.g.*, bars, tubes, rolled joints. A section on the strength of materials is full of useful formulæ and tables. We notice that a paragraph devoted to Hadfield's steel does not allude to its non-magnetic quality. A short section gives some rather antiquated information about electric transmission of power; a brief and very disparaging paragraph deals with electrical propulsion on railways; and one on electric traction is confined to a brief description of the Bessbrook-Newry line. The sections on mechanical principles and heat are very valuable, but we have no space to enumerate all the best parts of the contents. The section on the measurement of a stream of water is open to the same criticism which was applied in these columns by Mr. Geipel to Mr. Wilson's article, viz., that no reference is made to the correction for contraction at the edge of the bay, and no allusion is made to the V notch. In a book professedly for mechanical engineers, the concluding section on electrical engineering, which has been contributed by another author, might well have been omitted altogether, especially as it is altogether inferior to the rest of the work. A paragraph on accumulators says that "the acidulated water contains 25 per cent. of sulphuric acid," and does not give a word about the specific gravity. The precept that "the charging electromotive force should not exceed the electromotive force of the accumulator by more than 5 per cent." would have been welcomed as evidence by Mr. Lane Fox in the recent trial. "The accumulator cells," we are told, "should be kept in as dry (but not warm) situation as possible." The experience of central station managers is opposed to this. The diagrams from the earlier edition of "Dynamo Electric Machinery" are reproduced, showing the connections of dynamo fields, together with some of the least useful formulæ of that work. Many of these refer to efficiency, and after all, we read that "a good dynamo should have a commercial efficiency of at least 50 per cent." With the exception of the strictly mechanical tables of, say, telegraph wires, the whole of this section might well be omitted, especially as Mr. D. K. Clark does not seem to entertain a very high opinion of electrical engineering. As a mechanical engineer's pocket-book it is a most important addition to its class. The binding and type are of the very best, and may be said to be both comfortable and handsome. It opens like an ordinary book, but having rounded corners can easily be carried in a fairly roomy pocket, if necessary.

Lantern Slides of Faraday's Original Apparatus.

It is always interesting to see the actual tools with which great workers have worked, and to handle and re perform classical experiments with the very means with which some original genius first obtained a glimpse of unexplored regions of fact. When the pathway has become worn by the passage of many feet we are often unable to realise the slender clue which conducted the first explorer to the mountain top; and an intelligent student will always, therefore, appreciate an opportunity of examining the historical facts of the science he is studying. The next best thing to seeing the objects themselves is to see good photographs. We have before us a series of twelve lantern slides, prepared by Miss K. M. Reynolds, giving actual photographs of each of the principal pieces of apparatus employed by Faraday in the discovery of electromagnetic induction. These rings of iron, pasteboard tubes wrapped with hand-covered wire, and other relics treasured in the museum of the physical laboratory of the Royal Institution, have been separately photographed on glass (by permission), and Miss Reynolds has arranged a set of slides which will be found useful to teachers and lecturers. The set also includes a photograph of Faraday's historic magnets, with which the diamagnetic experiments and the magneto-optic work were performed, and a view of the laboratory and lecture theatre. The set of twelve lantern slides can be procured directly from Miss Reynolds, Southover, Heene, Worthing (price £1), and appended to each slide is a reference to the passage in the "Researches on Electricity" in which mention is made of the object represented. J. A. F.

Electrical Instrument Making for Amateurs. By S. R. Bottone. Fifth Edition. 1892. (London: Whittaker and Co.)

If an amateur were already a fair electrician and passable workman he might get a few useful hints in rough instrument making from the above book. To the beginner, for whom it is apparently written, it should only be given on the understanding that he is to accept no theoretical statement in it unless confirmed by some good authority, and is not to place too great reliance on the practical directions. Without such warning he might think that it was currently accepted that "according to our present knowledge the phenomena we group together under the name of electricity (*sic*) are simply manifestations of a peculiar mode of motion of atoms" (p. 121); or that "the arc itself sets up a back current (!), having an E.M.F. of 39 volts." He might also believe that a good rule for safe working current is to allow 2,000 amperes per sq. in. for copper of any diameter (between Nos. 6 and 22 at any rate), irrespective of depth of winding,

Digitized by Google

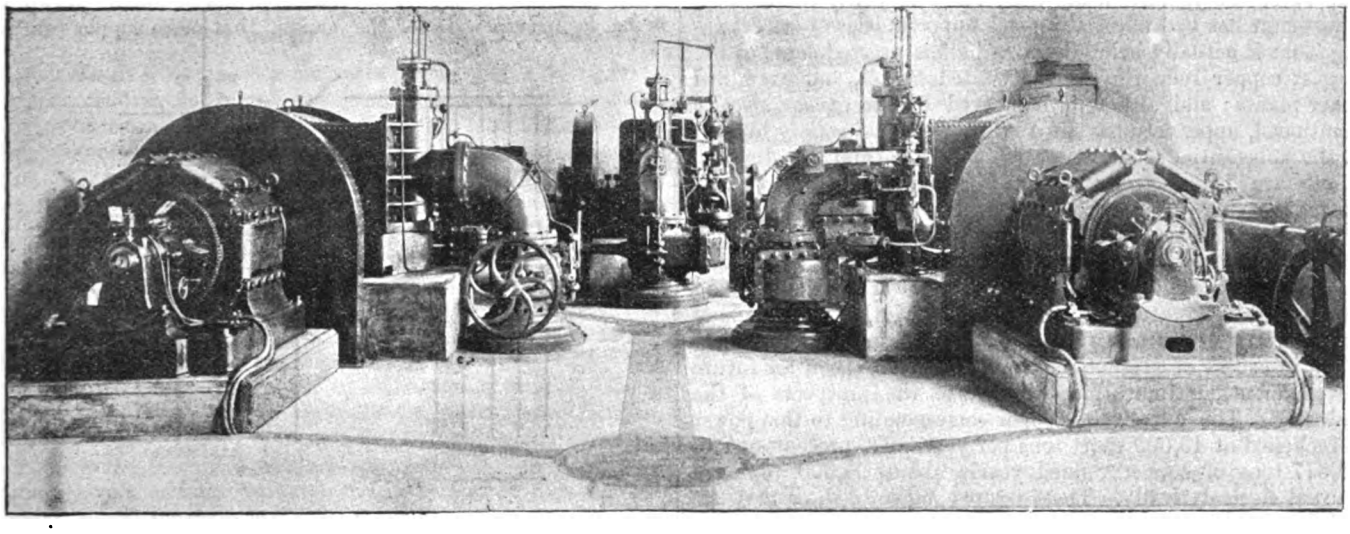
or whether it is to be used on a field magnet or an armature. The author is careful to state, however, that this only refers to *commercial* copper—he has tested samples of pure copper, which will carry nearly twice as much (pp. 113-200). As to practical instructions, the amateur *may* make a good and tight job of a three-cell accumulator box made out of sheet gutta-percha sealed up with a hot poker—on the other hand, he may not; but we are certain he will never live long enough to finish calibrating an ammeter in the way Mr. Bottone tells him to (p. 118). As an example of how to go about a simple and straightforward job in the most difficult and hopelessly unpractical way we have never yet seen its equal.

Professional Papers of the Corps of Royal Engineers. Edited by Captain W. A. GALE, R.E. Vol. XVII. (Chatham: Royal Engineers Institute.)

This volume, which is chiefly devoted to a Paper by Major E. C. S. Moore on Sanitary Engineering, contains some useful information relating to Webster's process of electrolytic sewage purification, including a report by Sir Henry Roscoe.

ELECTRIC LIGHTING IN SWITZERLAND.

There has recently been installed at Geneva a gigantic water-power plant. The turbines, which are situated on a small island in the middle of the Rhone, are principally used for furnishing power to a central station supplying the electric light to the town. It was found necessary to place this station 350 metres above the hydraulic house, resulting in an unavoidable loss of power. The Société d'Appareillage Électrique of Geneva have just terminated negotiations for the entire lighting of the town by electricity; and it would not be out of place to say something about their present plant, which will soon be known as the Ile at Geneva, contains eight dynamos, giving 600 amperes at 110 volts, and two extra dynamos of 115 E.H.P. The distribution is carried out on the three-wire system. Each cable encloses three separate conductors of the same size, and the current generated by the central station is delivered by five special feeder cables. The five feeders have a total length of some 3,000 metres. The distributing mains are about 3,500 metres long. Some 2,000 metres of other cable brings the total length up to some 25½ kilometres. The whole of the cables are underground.



View of a portion of the Geneva Hydraulic Electric Lighting Station.

doubled and trebled to meet the requirements of the place; Geneva will then have the largest installation in Switzerland.

In 1708 Geneva had a hydraulic plant installed on the left arm of the Rhone. The last vestiges of this disappeared in 1884, on the deepening of the river; and the present magnificent hydraulic station was commenced in 1883, under the direction of M. Turettini, the pumps being built by E. Wyss, of Zurich; Weibel and Briquet, of Geneva, furnished the overhead trolleys, the total horse-power capable of being developed by the turbines being nearly 5,000. The water is distributed at high and low pressure. For supplying the electrical central station, 12 to 15 centimes per H.P.H. is charged according to the consumption. Nearly 1,000,000 francs have been spent on the station and service. These hydraulic works, which belong to the town, have entailed an outlay of 6,000,000fr. and more, and 160,000fr. is required annually for maintenance. Still there is a yearly profit of some 200,000fr. In 1891 the total amount of water supplied was 27½ million cubic metres (6,050 million gallons).

A new project for utilising the power of the Rhone on a vast scale has just been presented to the authorities. The promoters state that they will put down machinery of the biggest type ever made, to realise 12,000 H.P. (15 turbines of 800 H.P). The site is 6 kilometres from Geneva, near the junction of the Rhone and Arre.

The present central station (see Illustration) on what is

Up to the present the lighting at Geneva is nearly all private. Some 10,000 glow-lamps are divided among nearly 350 subscribers. The total value of the central station and plant is put down at near 890,000fr. Salaries of electricians and other *employés* amount to 25,000fr. yearly, and an additional 25,000fr. per annum is spent on the water-power. The progress of electricity in Geneva is well shown in the annual report, 22½fr. per share being the last dividend declared. No fewer than 2,200 lamps are installed at the Geneva Theatre—a beautiful building, modelled after the Paris Opera House. A quarter of these are of 10 c.p., 160 of from 31 to 50 c.p., and the others are of 16 c.p.

The following are a few particulars of the supply prices:—per 8 c.p. lamp-hour, 4 centimes; 16 candles, 7 centimes; 32 candles, 12½ centimes; 50 candles, 18 centimes; 100 candles, 35 centimes. The arc lamp hour is rated at 10 centimes per ampere. The consumer has to pay for the installation of his meter, being charged at the rate of six francs for one meter, nine francs for two, twelve francs for three, and so on, increasing three francs for every additional meter. The 12-ampere meters cost 25 francs yearly, 25 amperes 30 francs, 50 amperes 40 francs, and 100 amperes 50 francs. These prices include maintenance. Subscribers have to pay a minimum annual sum of 150 or 250 francs per year per lamp, according to the nature of the places lighted. Payments are made monthly, persons who pay promptly are allowed a discount of from 5 to 17 per cent., according to their agreement.

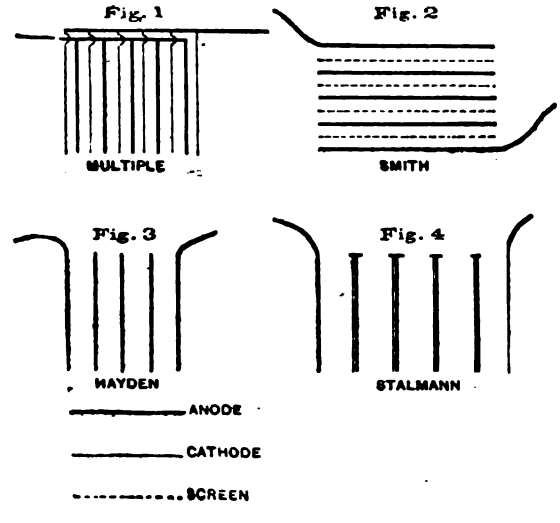
AMERICAN PRACTICE IN THE ELECTROLYTICAL REFINING OF COPPER.

Much needless mystery has been made about the details of the electrolytic refining of copper on a large scale, to the undoubted detriment of exact knowledge on the subject, and, consequently, to the money interests of those practising it. The reason is indicated in Dr. Gore's work on the "Electrolytic Separation of Metals," published in *The Electrician* Series, and may be assigned to the ignorance of manufacturers, of existing information open to all, and their consequent belief that the practical details each has worked out for himself are precious possessions not lightly to be parted with. Such inaccurate conceptions are inevitable wherever there is an indifference to, or ignorance of, general principles which alone suffice to link together isolated observations otherwise restricted in signification, or altogether incapable of interpretation. Under these conditions authentic information, from whatever source, is valuable, and its dissemination a praiseworthy undertaking.

The state of progress of the electrolytic refining of copper in America forms the subject of a Paper by Mr. F. B. Badt, read before the June meeting of the American Institute of Electrical Engineers—of which we have received an advance copy—in which the general though irrational dislike of publicity is illustrated by a quotation from Dr. Gore's book having the import of the remark made above, and is justly condemned. The writer has had unusually good opportunities of ascertaining what is actually being done, as he has erected some of the largest copper refineries in the United States, and examined other plants; and although hampered by the causes already mentioned, appears to have spared no pains to satisfy himself of the substantial accuracy of his statistics and conclusions. There are 14 electrolytic copper refinerles in the United States, varying in size from one having a dynamo capacity of nearly 500 kilowatts to the small installation where the refined copper is merely a bye-product from some other manufacture, using only some 6 kilowatts, the total power available being about 1,800 kilowatts. It must be stated that the whole of this power is not in use, plant having been, in some cases, put down in excess of present requirements in provision for future development, an indication in itself of the prospects of the industry. The output of copper corresponding to this power is reckoned at 43,000 short tons per year. At present out of 78,847 tons of copper refined yearly about 25,000 tons are treated electrolytically. These figures suffice to show that the industry is of considerable dimensions, and is not a mere addendum to the ordinary dry method of copper refining.

The arrangement of electrodes in favour in the United States refineries frequently exhibits a departure from the ordinary multiple system, special methods, named after their inventors, being in vogue. They are shown diagrammatically in the accompanying figures, together with the multiple disposition (Fig. 1) for comparison Fig. 2 represents the Smith arrangement, in which the electrodes are placed horizontally, a screen of cotton cloth being interposed between each pair. The top plate is made an anode and the bottom plate a cathode, the intermediate plates being unconnected directly to the dynamo. In consequence the upper surface of each plate becomes a cathode and the under an anode, the plates growing on the upper side and being eaten away on the under, until the whole of the impure metal has been dissolved and an equivalent of pure copper substituted for it. The impurities which do not dissolve are separated in the ordinary way, and are prevented from contaminating the clean freshly deposited copper by being caught on the screens of cotton cloth. Two refineries representing an output of 1,560 tons per year use this method. The Hayden process, which is cursorily mentioned by Gore ("The Electrolytic Separation of Metals," p. 186), is illustrated at Fig. 3, and differs from the Smith arrangement only in having the electrodes placed *vertically* instead of *horizontally*, thereby dispensing with the necessity for screens. It is in use in the refinerics having a capacity of 18,000 tons per year. In each of these devices the disadvantage accrues that the anode has to be completely dissolved and built up again from the other side before it, or rather the cathode which has replaced it, can be removed and worked up as refined copper; and to ensure that this is the case and that there is no crude copper representing the remainder of the former anode, the process must be carried on somewhat farther than would be necessary if the anode and cathode were not one and the same piece of metal, causing a certain wasteful expenditure of current in merely transferring pure copper from one plate to another if the limit be in the slightest degree overstepped. This difficulty is overcome by the plan adopted by Stalmann, who uses the same vertical arrangement as Hayden, but instead of plates of crude copper between the end anode and cathode, employs composite plates consisting of a plate of the crude and a plate of the refined metal bolted together and so placed that the pure serves as the cathode of each intermediate composite plate, and the crude as the anode. There is thus no risk of removing a plate of metal, supposed to be refined, to which a portion of the crude is still attached, as the separation between the two is mechanically precise. The method is quite new, and is in use in only one factory at present, the capacity of which is 4,200 tons per year, all of which, however, is not worked by the Stalmann system, but partly by the multiple method. Should experience show that no unforeseen difficulties arise from the substitution of either of these arrangements for the well-tried multiple, the further adoption of one or other of them is probable, for they all present the advantage of needing no external connections for the intermediate plates, and the first two dispense with the use of a separate sheet of pure copper for the cathode, and thus save a certain appreciable amount of capital being locked up. As for the claims that more copper can be refined per horse-power, that less copper is idle and so forth, they are of course quite untenable. It is, as Mr. Badt rightly reiterates, theoretically possible to refine an infinite quantity of copper with a finite expenditure of energy; but full advantage can never be taken of this fact, as it also involves the handling of an infinite quantity of copper, the interest upon the money value of which would be quite a considerable item. In fact, economy of power and restriction of the stock of copper lying idle are incompatible with each other, and local circumstances must always determine which of the two is to be aimed at. Where power is cheap, efficiency in its expenditure can be sacrificed to compactness of plant and rapidity of turnover; where it is dear, efficiency must be studied even at the expense of holding a large stock of copper, a metal prone to market fluctuations.



The circulation of the electrolyte is generally effected in this country by the cascade system, but in America a plan, said to be preferable, is in use, consisting in having a trough run from end to end of the refinery, and each tank supplied therefrom by means of an indiarubber pipe. There is also an alternative to the overhead tank, fed by pumps or an injector, with which we are here familiar, avoiding the trouble caused by the former, and the dilution produced by the condensation of the steam from the latter. In this two collecting tanks are used, and as soon as one is full it is closed air-tight, and air driven in it by a small compressor worked by an electric motor until a pressure of about 25lb. is obtained, sufficing to drive

Digitized by Google

the solution up into the troughs, the other tank receiving the overflow. With Smith's arrangement of electrodes it is claimed that no circulation is required, as the free acid from the horizontal surface of each cathode rises through the screen to the anode surface next above it, and acts uniformly thereon. A curious convention obtains in the American copper refining trade anent the purchase of matte at a price influenced by its contents of silver. When the amount of silver is below 30 ounces per ton the price is not raised, but an increment in accordance with the total amount of silver is made when this limit is passed. Consequently copper refiners naturally prefer to buy matte containing rather less than 30 ounces of silver per ton.

The following estimate of the cost of a refinery for an output of 1,000,000lb. of copper per month will be found interesting :—

Building	$30,000
Pavement (asphalte)	2,000
Pipes for steam heating	4,000
Vats	6,000
Lead for lining vats, collecting troughs and tanks	28,000
Lead burning	1,500
Copper conductors	11,000
Rails for overhead blocks for handling plates	2,000
Sulphate of copper	3,500
Sulphuric acid	1,000
Steam injector or pump, or air compressors	1,000
Electric generators, switchboard, instruments	30,000
Shafting and belting	3,000
Total	$123,000

It will be seen that this estimate assumes that water-power will be used for driving the dynamos. In the event of steam-power being required another $20,000 must be added for the cost of engines and boilers. Labour, but not freight, is included in the figures given above. The further amount of capital represented by the copper under treatment is about $80,000, though this will be greater where power is dear, for the reasons already detailed. The total outlay is, therefore, $223,000—that is about £45,000—a capital sufficiently large to show that the setting up of a modern electrolytic copper refinery is an undertaking of some magnitude, unless indeed the copper be obtained merely as a bye-product of some larger industry.

A METHOD OF TESTING THE EFFICIENCY OF TRANSFORMERS.

BY W. E. SUMPNER, D.SC.

The ordinary methods of testing the efficiency of transformers are subject to the defect that the quantity measured is only arrived at by an indirect process, by comparing the values of the input and output of the converter; and as these values are difficult to measure accurately, and are of very nearly equal magnitude, any determination of their ratio is subject to considerable error unless very careful observations are made. In Dr. Hopkinson's recent tests of two Westinghouse transformers, an account of which has just been published in *The Electrician*, this difficulty has been avoided by making the measurements in such a way that the *losses* occurring in the transformers are, as far as possible, measured directly; and the efficiency is deduced by comparing these losses with the output. If W is the load of the transformer in watts, and if w is the waste in watts occurring in the transformer at this load, the efficiency η of the transformer at this load is, of course,

$$\text{efficiency} = \eta = 1 - \frac{w}{W};$$

and, as the efficiency of transformers is something like 95 per cent., the ratio of w to W is only about 1 to 20, so that an error of 1 per cent. in measuring either of these quantities only affects the efficiency η to one-twentieth part of 1 per cent. If, however, the two quantities we measure directly are the input W, and the output W—w, an error of 1 per cent in determining either of these quantities will make an error in η, which is of the same magnitude. As is well known, Dr. Hopkinson has made use of this principle with marked success in testing the combined efficiency of a dynamo and motor; and in the transformer tests just published the chief object has been to determine the losses w as directly as possible. But although the method used by Dr. Hopkinson in these alternate-current tests has yielded excellent results, it is far too complicated for common use, and it may be profitable to inquire whether a simpler method exists.

The distinguishing feature of Dr. Hopkinson's dynamo method is to couple a dynamo and motor together, to supply energy to one, by which it is transferred to the second, which returns it again to the source. The balance of energy supplied by the source is thus no more than the waste of energy which takes place in the double transformation, and a measurement of this amount of energy at once gives the quantity w. Now can we arrange two transformers in such a way that the energy taken by the first from the distributing mains is transferred to the second, and from this back to the mains again? In order to answer this question we must consider the various ways of coupling two transformers together. Since we may connect the primaries in parallel or in series, and are also at liberty to couple the secondaries in either of these ways, we have altogether four cases to consider, which are represented in Figs. 1 to 4.

In the first place, let us take the case of Fig. 1, in which the primaries c_1 c_2 are in parallel, and the secondaries C_1 C_2 in series, a non-inductive resistance being inserted either at R or r for the purpose of regulating the currents. It is easy to see that this arrangement is useless for our present purpose,

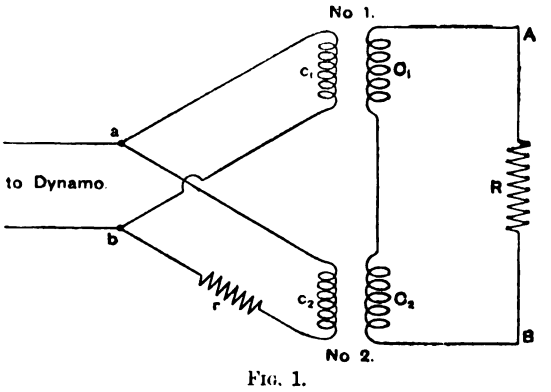


FIG. 1.

as the energy, instead of circulating through the transformers back to the mains, is spent in the non-inductive resistances. Suppose, for definiteness, that the mains a b supply at 100 volts, and that the transformers are each intended to convert a maximum load of 4,000 watts from 100 volts to 2,000 volts. Then, when the full-load currents are flowing through the transformer, it will be seen that 8,000 watts will be expended in heating either R or r. In the former case (r cut out) the potential between the points A and B will be 4,000 volts, and the current 2 amperes; and in the latter case (R being cut out) the potential on the resistance r will be 200 volts and the current 40 amperes. It is true that we can with safety cut out of circuit both r and R, provided we sufficiently lower the voltage on the supply mains a b; and if we arrange this voltage so that the currents in the transformer are the full-load currents, the energy supplied by the mains is all wasted in the transformers. But this waste is not the actual loss occurring in the transformers under the normal full-load conditions. The currents in the coils, and thus the waste in the copper, are no doubt the same; but the iron core is subjected to a very much smaller induction than under ordinary working conditions, so that the iron losses will be very different from those which actually occur in practice. In fact, the voltage induced in this secondary circuit, instead of being 4,000 volts, is merely that necessary to drive the secondary current (2 amperes) through the resistance (15 to 20 ohms) of the two secondary coils.

Let us therefore proceed to the next case, illustrated in Fig. 2, in which both primaries and secondaries are in parallel. If the transformers are exactly alike nothing will happen in consequence of completing the secondary circuit, as the secondary

Digitized by Google

voltages exactly neutralise each other. Inserting a resistance at R will not alter this state of things, since no current flows in the secondaries. Putting a resistance in at r will produce a slight change in consequence of the magnetising current taken by the primary c_2. This current will be diminished, and, in order to keep up the voltage on the transformer terminals, a current will flow in the secondary circuit, which will act as a load current as far as transformer No. 1 is concerned, but will act as a magnetising current with regard to transformer No. 2. Altering r will thus only alter the proportion of the excitation of the core caused by the currents in the coils c_2 C_2. Suppose, however, that the two transformers are not exactly alike, and that transformer No. 1 converts from 100 to 2,100 volts, while transformer No. 2 only converts from 100 to 2,000 volts; then there will be a balance of 100 volts available for driving a current round the secondary circuit considered merely as a non-inductive resistance, and if we insert a resistance in either the primary or secondary circuit we can, by adjusting the amount of this, regulate the currents to be what we please. Suppose we choose to insert the resistance in the secondary circuit, then, by adjusting R, we can make the current in the secondary equal to 2 amperes, the full load current. Taking the resistance of each of the secondaries to be 10 ohms, it will be seen that in the case considered 40 volts will be absorbed in the coils, and 60 volts will be left for the resistance R. As a matter of fact, less than this will be absorbed by R, owing to the drop in the transformers due to

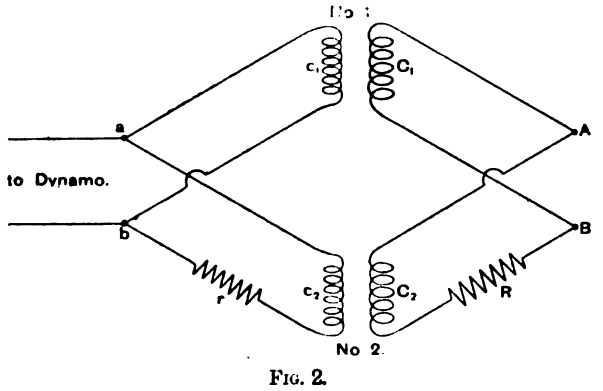

FIG. 2.

magnetic leakage, and the resistance of the primaries; but assuming 60 volts to be the actual potential on R, the resistance of R will be 30 ohms, and only 120 watts will be absorbed. But each of the transformers is now working at full load, and 4,000 watts are being transferred from the mains to the secondary circuit, across transformer No. 1, and, with the exception of the losses in the converters, from the secondary circuit to the mains again across transformer No. 2. The actual energy taken from the mains thus only corresponds with the losses in the transformers, together with the losses occurring in the resistance R. Supposing the transformers have an efficiency of about 95 per cent. the losses occurring in them at full load will amount to about 400 watts, so that the power taken from the mains will be 520 watts, to supply these losses, as well as the waste of 120 watts in the non-inductive resistance. Whether it is more convenient to insert the non-inductive resistance in the low volt or in the high volt circuit, and whether it is preferable to use the fine-wire coils of the converters in the positions C_1 C_2, or in the positions c_1 c_2, will entirely depend upon the means available for testing. But, in any case, it will be easy to measure, with ordinary workshop instruments, the power supplied by the mains, and also that wasted in the non-inductive resistance, with a fair degree of accuracy. The loss of power in the transformers, which we have denoted by w, can thus be measured almost directly, and the load W is given with quite sufficient accuracy by multiplying together the voltage and current of any one coil of the transformers. Even if an error of 5 per cent. is made in estimating both w and W, the efficiency found will not differ from the true value by any appreciable amount. The efficiency of the double conversion is

$$1 - \frac{w}{W},$$

and the efficiency of each transformer is, therefore, the square root of this quantity. As the ratio of w : W is small, not more than 1 : 20 corresponding with a transformer efficiency of 95 per cent., the value of the efficiency η is given quite accurately enough by the formula

$$\eta = 1 - \tfrac{1}{2}\frac{w}{W} - \tfrac{1}{8}\frac{w^2}{W^2},$$

and an error of 10 per cent. in estimating the ratio of w/W does not alter the value of η by more than one quarter per cent. The method just described should, therefore, prove economical, simple, convenient, and accurate. It is at once applicable to any two transformers, which, when placed across the same mains, yield voltages on their secondaries, differing at full load by at least twice the drop of the secondary voltage of either transformer as its load is increased from nothing to its full value. Unfortunately, for this method two transformers of the same type made in the same works, will not differ by as much as this; and in order to apply the method in the case of two exactly similar transformers it is thus necessary to devise some means of supplying energy to the secondary circuit formed by placing the two secondaries in parallel.

A very simple way of doing this appears to be to provide a small additional transformer, whose output at full load is about equal to the waste of power occurring in the two large transformers at full load. If the primary of this small transformer be connected in series with an adjustable resistance x, across the supply mains indicated at the left of Fig. 2, and, if the secondary of this transformer be placed in series with either

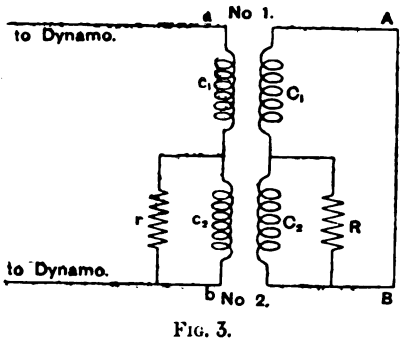

FIG. 3.

the coil C_2 or the coil c_2, in place of the former resistances R, r, respectively, the energy supplied by this secondary, which can be regulated by altering x, will generate any desired current in the big transformers. It will not be necessary to measure the losses in, or to know the efficiency of, the small transformer. In fact, the goodness or badness of this little transformer is a matter of indifference. All that need be done is to measure the losses in, or to know the efficiency of, the small transformer. All that need be done is to measure the *output* of the small secondary, together with the amount of energy taken from the mains by the two large transformers whose primaries are connected with the points a b. The sum of these two quantities will at once give the loss of power, w, in the large transformers, and the output W can of course be measured as easily as before. This modification of the method is in fact preferable to the one already described, not only because it is more economical, but because the quantity w is estimated by adding two measured quantities, and not, as before, by subtracting them. On this account w can be determined with greater accuracy. The particulars of the small transformer can be at once deduced from the primary volts, the amount of waste in the transformers, and the current in the circuit in which the secondary is placed. In the case we have considered, of two 4,000-watt transformers converting from 100 to 2,000 volts, and each absorbing about 200 watts at full load, the full load of the small transformers need not exceed 400 watts. If low potential mains are used for testing, the primary should take 4 amperes at 100 volts, and the secondary should either take 40 amperes at 10 volts, or 2 amperes at 200 volts, according as it is to be used in the low-volt or high-volt circuit. If high-potential mains are used the corresponding details can as easily be found.

As part of the energy used up in the large transformer is supplied direct from the mains, the full output of the small transformer need not, however, be as much as 400 watts. It is of some interest to see what determines the amount of energy supplied direct from the mains, as compared with that given out by the secondary of the small transformer when placed, say, in the secondary circuit C_1 C_2. This relation depends on the characteristic curves of the two large transformers. If V is the potential of either of the secondaries C_1 C_2 when on open circuit, the voltage of these coils when a current A is flowing through them is $V - v_1$ for the coil C_1, and $V + v_2$ for the coil c_2. The voltage supplied by the small transformer will be $v_1 + v_2$, and the power put in will equal $A(v_1 + v_2)$. Now, $v_1 + v_2$ will increase a little more rapidly than A, so that the power supplied by the small transformer will increase a little faster than the square of the current, and will be, approximately, equal to the losses occurring in the copper of the large transformer. On the other hand, the current taken from the mains will be the difference of the currents in the coils c_1 and c_2, and will be nearly constant for all loads. The power taken from the constant potential mains is thus nearly constant, and approximately represents the losses occurring in the iron of the transformer. If the iron losses are about equal to the copper losses, the small transformer, in the case we have considered, need only have an output of 200 watts.

Having now examined the parallel arrangements of the primaries indicated in Figs. 1 and 2, we may next consider the result of connecting the two primaries in *series*, as indicated in Figs. 3 and 4. It will, however, be unnecessary to consider

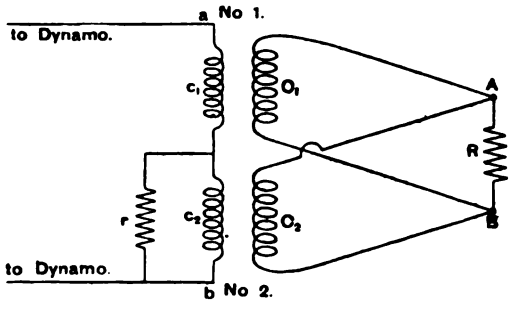

FIG. 4.

these methods at great length, as investigation soon shows that they are only suitable for transformers intended to regulate for a supply of energy on constant-current mains. Prof. Ayrton, in conjunction with the present writer, pointed out more than a year ago that to any electrical method of measurement an analogous method can be found in which amperes are measured instead of volts, and volts are measured instead of amperes. In fact, if the description of any method is taken, and wherever a word occurs denoting current, the word "voltage" is substituted, and *vice versâ*, the result will be the description of a different method analogous to the former. Parallel arrangements convert into series ones, and series arrangements into parallel. Applying this process we at once convert Fig. 2 into Fig. 3 and Fig. 1 into Fig. 4. Just as in Fig. 1, we must not short-circuit the resistance R (or r) if constant potential is maintained between $a\,b$, so in Fig. 4 we must not open-circuit the resistance R (or r) if constant current is supplied by the mains. In the former case we should cause dangerously large currents to flow through the coils; and in the latter the voltages taken by the coils would become excessive. Also, just as the arrangement of Fig. 1 was found unsuitable for our present purpose, because the energy transferred by constant potential transformers was all absorbed in the added resistance, so it will be found that constant-current transformers cannot be well tested by the arrangement shown in Fig. 4, for exactly the same reason. In the same way, all the remarks made above with reference to the apparatus denoted by Fig. 2 can be at once translated to apply to Fig. 3. If the transformers are exactly equal there is no potential available to send a current through the resistance R, and altering r will only alter the state of induction of the core of the transformer to which it is shunted. If the change ratio for currents differs for the two transformers, the non-inductive resistance will absorb the difference of the currents, and by altering its amount the potentials of the transformer terminals can be made to rise to their full load values. One transformer will work the other, and the transformer losses can be measured in an exactly analogous manner to that already described. Also, to apply the method to two transformers which are exactly alike, it will be necessary to use a small transformer, whose full load is about equal to the loss of energy in the large transformers at full load. This small transformer must have its primary placed, not in parallel, but in series with the primaries of the two large transformers; and the secondary must be placed, not in series, but in parallel with either the primary or secondary coil of one of the transformers. In fact, as before, it must replace either r or R.

TEST OF TWO 6,500-WATT WESTINGHOUSE TRANSFORMERS.*

(*Concluded from page 200.*)

If the transformers had been exactly equal, the potentials for the two given by Table I. would have been equal, though they would have differed a little in phase owing to the lines of magnetic induction which pass through the non-magnetic space between the two coils of the transformer.† The difference shows that No. 1 transformer has a ratio of transformation slightly greater than No. 2. If we correct the potential of either No. 1

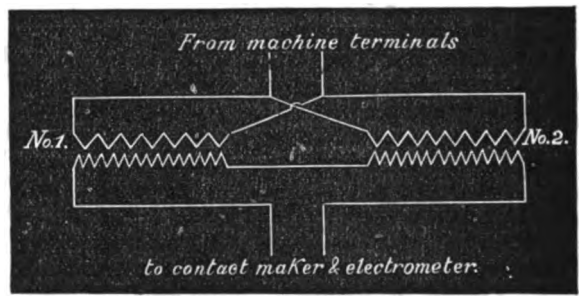

FIG. 8.

or No. 2, there still remains a difference between them, but this difference will be greatest about when the potentials are *nil*. This is due to the lost induction just referred to. In order to check the conclusion that the two transformers are not precisely equal, they were directly compared as in Fig. 8. The transformers were coupled parallel as in Fig. 8, and the difference of potential of the two high-potential coils was measured, the value of its square root of mean square was 12·5 volts, the potential of the transformer being 2,400. This does not necessarily imply that the potentials of the two transformers differ by one-half per cent., it may be largely due to a difference of phase between the two.

The current supplied to the No. 1 transformer is to be accounted for by the currents necessary to magnetise the two transformers, and by the local currents in their cores. To ascertain the former, the curve of magnetisation of one of the transformers was determined by the ballistic galvanometer for nearly the same induction as in Table I. The changes of current supplied by a battery being made by a reversing switch, or by suddenly introducing resistance into the primary circuit, and the consequent changes of induction being measured by the galvanometer. The tardiness of change of current in the transformer due to its self-induction was sufficiently reduced by using many cells and a considerable resistance. The results are shown in Curve V. for a single transformer. In this curve, the abscissæ are the currents in the thin coil of the trans-

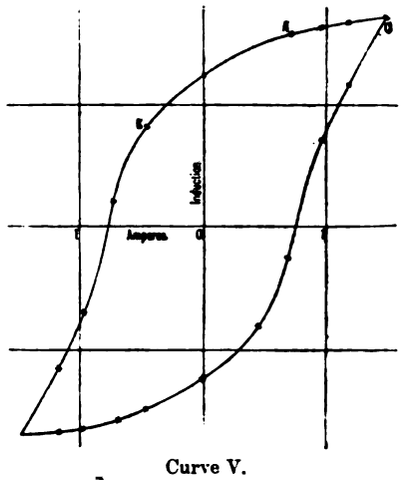
former, divided by 24, to reduce it to the same effect as it would have had if it had been in the thick coil. The ordinates are the inductions as measured by the kick on the galvanometer, but reduced to a scale to make them directly comparable with the volts when the transformer is used with an alternating current. These results are not given in absolute units. The procedure to determine points on the curve was, first, pass the maximum current corresponding to the point C, next suddenly diminish the current by inserting suitable resistance in the thin-coil circuit, and observe the kick, the drop of ordinate from C to A corresponds to the kick, and the abscissa of A is the current after it has been reduced. Next reverse the current, and observe the kick, the kick corresponds to the further drop



Curve V.
